Contributing Studies

GenOMICC and ISARIC4C

Patients were recruited to the GenOMICC (Genetics Of Mortality In Critical Care) study in 224 UK intensive care units (<https://genomicc.org>). All cases had confirmed Covid-19 according to local clinical testing and were deemed, in the view of the treating clinician, to require continuous cardiorespiratory monitoring. In UK practice this kind of monitoring is undertaken in high-dependency or intensive care units. Additional Covid-19 confirmed hospitalised cases were recruited through the International Severe Acute Respiratory Infection Consortium (ISARIC) Coronavirus Clinical Characterisation Consortium (4C). Current and previous versions of the study protocol are available at <https://genomicc.org/protocol/>. All participants gave informed consent.

Participants were recruited to the mild Covid-19 cohort on the basis of having experienced mild (non-hospitalised) or asymptomatic Covid-19. Participants volunteered to take part in the study via a microsite and were required to self-report the details of a positive Covid-19 test. Volunteers were prioritised for genome sequencing based on demographic matching with the critical Covid-19 cohort considering self-reported ancestry, sex, age and location within the UK

Whole genome sequencing summary statistics

8794 critically ill individuals and 1809 mild Covid-19 controls were sequenced through the GenOMICC study. To increase control numbers, we added general population controls from 100k-genomes cohort. Participants were enrolled in the 100,000 Genomes Project from families with a broad range of rare diseases, cancers and infection by 13 regional NHS Genomic Medicine Centres across England and in Northern Ireland, Scotland and Wales. For this analysis, participants for whom a positive SARS-CoV-2 test had been recorded as of March, 2021 were not included due to uncertainty in the severity of Covid-19 symptoms. Only participants for whom genome sequencing was performed from blood derived DNA were included and participants with haematological malignancies were excluded to avoid potential tumour contamination. DNA extraction, sequencing, ancestry estimation, kinship estimation, principal components calculation and QC pipelines were performed as described in Kousathanas et al.¹ GWAS was performed using a 2-step logistic mixed model regression approach as implemented in SAIGE v0.44.5 for single variant association analyses with sex, age, age squared, age by sex interaction and 20 principal components as covariates. The principal components were computed separately by predicted genetic ancestry (i.e, EUR-specific, AFR-specific, etc.), to capture subtle structure effects.

Genotype summary statistics

8143 Critically ill cases recruited through the GenOMICC, and 888 additional Covid-19 confirmed hospitalised cases recruited through ISARIC4C were genotyped. DNA extraction, sample QC, genotype QC, kinship estimation, ancestry estimation and imputation were performed with the pipelines described in Pairo-Castineira et al.².

After these steps and removing individuals with whole genome sequencing data available¹ there were 1900 unrelated individuals assigned to the European ancestry group, 259 unrelated individuals assigned to the South Asian ancestry group, and 144 unrelated individuals assigned to the African ancestry group. Individuals from East Asian and American ancestries were removed from the analysis because there were less than 100 cases for each of them.

Principal components were calculated as in our previous work² for all GenOMICC participants and UK Biobank individuals, as well as, for each ancestry group individually and are illustrated in Supplementary Figure 1 and Supplementary Figure 2 respectively.

UK Biobank participants from a subset with no relationships up to third degree were considered as potential controls if they were not identified by the UK Biobank as outliers based on either genotyping missingness rate or heterogeneity, and their sex inferred from the genotypes matched their self-reported sex. After excluding participants who had received PCR tests for Covid-19, based on information downloaded from the UK Biobank on 27/01/2022. For each GenOMICC individual we considered the subset of UK Biobank individuals with matching assigned ancestry group and sex, and selected the five closest, based on euclidean distance in the space of the first six ancestry specific genomic principal components, as controls.

Figure 1: Genomic PCA plot showing the first two principal components for the combination of all UK Biobank and GenOMICC participants. Assigned ancestry group for GenOMICC participants is indicated through colour.

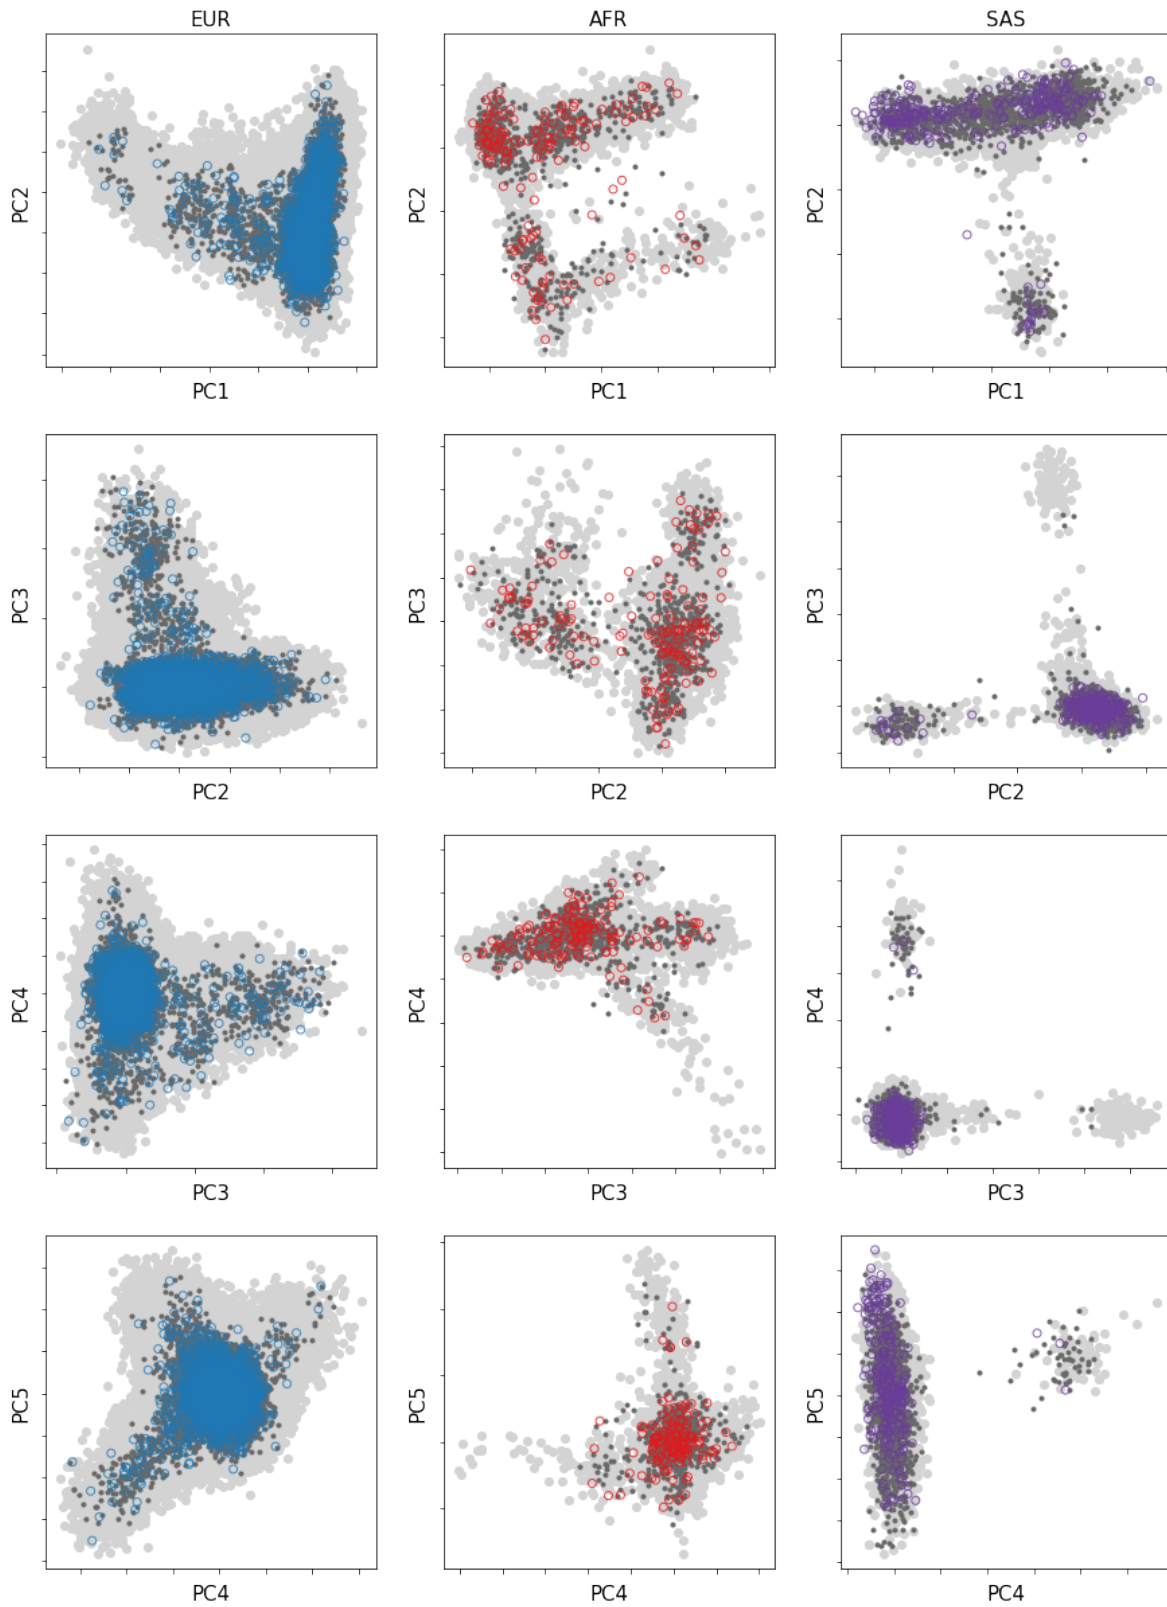

Figure 2: Genomic PCA plots showing the distribution of all cases and controls for the first 5 principal components for each ancestry group. Cases are shown as coloured open circles: European (EUR, blue), African (AFR, red), and South Asian (SAS, purple). Controls are dark grey closed circles. UK Biobank population background is shown as light grey closed circles.

Test for association between case-control status and allele dosage at the was performed by fitting a logistic regression model using PLINK 2.00 with sex, age, mean-centred age², deprivation score decile of residential postcode, and the first 10 ancestry specific genomic principal components as covariates. GWAS results for individuals from European ancestry were filtered for $MAF > 0.01$, $HWE P - value > 10^{-50}$, and genotyping rate > 0.99 and imputation score > 0.9 in both GenOMICC and UK Biobank. To avoid bias for using a different genotyping array and imputation method between cases and controls MAF for each SNP was compared between UK Biobank and gNOMAD non-Finnish European individuals, and SNPs were removed from following two rules (1) In SNPs with $MAF > 0.1$ in gnomAD, an absolute difference in MAF of 0.05 between gnomAD and UK Biobank controls; (2) in SNPs with $MAF < 0.1$ in gnomAD, a difference in MAF of $> 0.25 \times MAF_{gnomad}$ between UK Biobank controls and gnomAD. After this filter, a further LD-check filter, following Kousathanas et al¹ was used to clean the GWAS from false positives. GWAS analyses of individuals of South Asian and African ancestries were filtered for variants filtered for a MAF in UK Biobank corresponding to the same ancestry > 0.05 and then for the SNPs that passed quality control in the European GWAS. For the Critical-illness GWAS, ISARIC4C hospitalised individuals that did not fulfill the critical illness criteria were removed from the analysis with their matched controls, leaving 101 Covid-19 critically-ill cases from African ancestry, 200 critically-ill cases from South Asian Ancestry and 1487 critically-ill cases from European ancestry and 5 matched controls for each case.

BraCovid/GenoMICC Brazil

Covid-19 patients were enrolled after hospitalisation in one of the following tertiary care centers in the metropolitan area of Sao Paulo, Brazil: Instituto do Coração, and Instituto Central do Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo. Non-hospitalised cases were selected by serological studies surveys for previous SARS-CoV-2 infection or SARS-CoV-2 PCR test among health professionals or the general population. After signing an informed consent, a sample of whole-blood already collected for in-hospital biochemical analysis or SARS-CoV-2 serology was used for genomic DNA extraction. DNA extraction, genotyping, imputation and QC pipelines are described in Pereira et al.³

GWAS of Covid-19 hospitalised cases versus Covid-19 positive mild controls was performed using a logistic regression model in PLINK 2.0 including age, sex, age, array type and four principal components as covariates. Due to the level of admixture and complex genetic structure present in the Brazilian population, three different ancestry subgroups were defined (European, African, Native American), and a fixed-effect meta-analysis was calculated using the plink meta-analysis routine³.

SCOURGE

In Spain, 11,939 Covid-19 positive cases were recruited as part of SCOURGE study from 34 centres in 25 cities.⁴ Study samples and data were collected by the participating centers, through their respective biobanks after informed consent, with the approval of the respective Ethic and Scientific Committees. The whole project was approved by the Galician Ethical Committee Ref 2020/197. Individuals were diagnosed as Covid-19 positive through a PCR-based test or according to local clinical and laboratory procedures. All cases were classified in a five-level severity scale. Two Spanish sample collections with unknown Covid-19 status were included as general population controls in some analyses: 3,437 samples from the Spanish DNA biobank (<https://www.bancoadn.org>) and 2,506 samples from the GR@CE consortium. DNA extraction, genotyping, imputation, ancestry estimation, kinship estimation and QC pipelines are described in Carracedo et al.⁴.

GWAS was performed by fitting a logistic regression models implemented in SAIGE. For the hospitalised meta-analysis the summary statistics of the hospitalisation vs non-hospitalised (mild cases and population controls) analysis were used. For the critical illness meta-analysis, the summary statistics of severity grade 3 and 4 as defined by SCOURGE⁴ vs population controls were used.

HGI release 6

In total 25 studies contributed to the A2 analysis, with 8779 cases and 1001572 controls and 43 studies contributed to the B2 analysis with 24274 cases and 2061529 controls without including 23andme data. All studies followed protocols approved by local Institutional Review Boards; All protocols followed

local ethics recommendations and informed consent was obtained when required Meta-analysis of all cohorts was performed with and inverse-weighting variance method as described by the Covid-19 Host Genetics Initiative⁵

In order to account for signal due to sample overlap we performed a mathematical subtraction from HGIv6B2 of the GenOMICC GWAS of European genetic ancestry and the BraCovid analysis, and a mathematical subtraction from HGIv6A2 of the GenOMICC GWAS of European genetic ancestry . Publicly-available HGI data was downloaded from <https://www.covid19hg.org/results/r6/>. The subtraction was performed using MetaSubtract package (version 1.60) for R (version 4.0.2) after removing variants with the same genomic position and using the lambda.cohorts with genomic inflation calculated on the GenOMICC summary statistics.

23andme

Participants were recruited from the customer base of 23andMe, Inc., a personal genetics company. All individuals included in the analyses provided informed consent and answered surveys online according to 23andme human subjects research protocol, which was reviewed and approved by Ethical and Independent Review Services, a private institutional review board (<http://www.eandireview.com>). Study participation consisted solely of web-based surveys, and different phenotypes were defined for disease severity: pneumonia, hospitalisation and respiratory support. DNA extraction, genotyping, imputation, ancestry estimation, kinship estimation and QC pipelines are described in Shelton et al.⁶. GWAS were performed for each phenotype and ancestry separately using a logistic regression using age, sex, age squared, a age:sex interaction and top ten principal components as covariates, as described in Shelton et al.⁶

For the hospitalisation meta-analysis we used summary statistics from the respiratory support or pneumonia phenotype against population controls GWAS from European, African and Latino ancestries. For the critically-ill meta-analysis we used summary statistics from the respiratory support phenotype against population controls GWAS. We filtered variants that passed internal 23andMe ancestry QC⁶ and had imputation score > 0.6 and with MAF > 0.005 .

Table 3: Conditional analysis for critical illness phenotype. Conditional analysis was calculated using EUR reference panel as most of the population from the analysis is from European ancestry. Chr: chromosome, Pos(b38): position on human genome build 38, Allele1: effect allele, Allele2: other allele, beta: effect, SE: standard error, P: P-value, beta_{cond}: beta in conditional analysis SE_{cond}: standard error in conditional analysis P_{cond}: P-value in conditional analysis LD_r: LD between SNP_i and SNP_{i+1} significant in conditional analysis, Gene: nearest or most plausible nearby gene
