

**S2 Table. Estimated incidence of dysosmia as a function of subject age and odorant concentration.**

Linear regression was performed on the coefficients and constants of three logistic regressions in table 1 (0.06%, 0.32%, and 3.2% from site 2) as a function of the log of test concentration. These two linear regressions<sup>1</sup> were used to obtain coefficients and constants for intermediate concentrations and were then used to calculate prevalence estimates as a function of age. Hyposmia occurs in the tail of the distribution of olfactory sensitivity in the population distribution and is a joint function of age and odorant concentration; thus, if hyposmia is defined as the least sensitive 12% of a sample, test concentrations can be selected for different geriatric or education settings. For example, 1% might be selected for a population over the age of 40 and would be expected to approximate the NHANEs (1) hyposmia data (Fig 1) generated using odor identification error rates; 0.56% might be used in college and university settings.

Age	Odorant Concentration (% n-butanol in water)							
	<u>3.2</u>	<u>1.8</u>	<u>1.0</u>	<u>0.56</u>	<u>0.32</u>	<u>0.18</u>	<u>0.1</u>	<u>0.056</u>
