18 **Short Title:** Indonesia Health Workforce Quantity and Distribution

19 **ABBREVIATION**

20 **HRH:** Human Research for Health; **HW:** Health Worker, **NHS:** National Health Services; **GP:**

21 General Practitioner; **UHC:** Universal Health Coverage

22 ABSTRACT

23 **Background:** Indonesia, the world's largest archipelago, faces unique challenges in distributing its
24 health workforce across its diverse geographic barriers, leading to disparities in health worker
25 number and distribution. By dissecting the distribution patterns and identifying areas of critical
26 need, the research seeks to inform policy interventions that can more effectively bridge the gap on
27 health worker quantity and inequity.

28 **Methods:** We conducted a descriptive analysis of healthcare workforce data across all 514 districts
29 in Indonesia. The study focused on five categories of health workers: General Practitioners (GPs),
30 medical specialists, dentists, nurses, and midwives. We calculated the health worker ratio to
31 determine the availability of healthcare workers relative to the population. To evaluate the
32 distribution of these workers, we employed the Gini Index as a measure of distribution equality.
33 Additionally, we conducted a comparative metric approach to assess both the quantity and the
34 equity of healthcare worker distribution across the districts.

35 **Results:** In Indonesia, the current health worker ratio stands at 3.84 per 1000 population, falling
36 short of the WHO's threshold of 4.45 for achieving 80% Universal Health Coverage. This shortfall
37 translates to a need for an additional 166,000 health workers. Our analysis reveals a varied
38 distribution of health worker categories: while midwives show a relatively equitable distribution,
39 specialists and dentists exhibit significant inequality, especially at the district level. The Gini Index,
40 used to measure this inequality, indicates greater disparities at the district level compared to the
41 provincial level. There has been notable progress in the distribution of medical specialists across
42 provinces, with the between-provinces Gini Index for specialists decreasing from 0.57 in 1993 to
43 0.44 in 2022. However, the inter-district Gini Index remains high at 0.53 in 2022, signifying a
44 concentration of specialists in major cities and provincial capitals.

45 **Conclusion:** This study shows that human resources for health in Indonesia suffer not only in
46 quantity but also in distribution. Our finding underscores the importance of considering inter-
47 province and inter-district disparities to tailor policies to tackle unique problems each region faces.

48 **Keywords:** Health Workforce; Quantity; Distribution; Gini Index

Evidence Before Study

- Prior research has established that the quantity and distribution of health workers are critical factors in improving life expectancy and are fundamental components of the health system.
- Following Indonesia's constitutional changes in 2001, which included the autonomy and decentralization of healthcare services, assessing the number of health workers at the district level has gained significant importance for determining national healthcare needs.
- There has been a notable gap in studies analyzing the quantity and distribution of health workers in Indonesia's district level. Previous research often missed the nuances of district-level challenges, focusing instead on broader, national-level assessments.

What This Study Adds

- **First National Study on Health Workforce:** This is the first study of health workforce quantity and distribution at Indonesia's National level. so this paper serves as a basic reference for future research
- **Quantitative Analysis of Distribution Equity:** Utilizing the Gini Index, the study quantifies the level of inequality in the distribution of healthcare workers, offering a clear metric to guide policymakers in assessing and addressing regional disparities.
- **Identification of Regional Variations:** The study highlights significant regional variations, with some provinces showing an inequitable distribution of health workers, demonstrating a critical need for increased healthcare personnel and better distribution strategies.
- **Dual-dimensional assessment:** The study introduces a quadrant comparative approach that simultaneously evaluates the quantity of healthcare workers and the equity of their distribution across Indonesian provinces. This dual-dimensional analysis is a significant methodological advancement, providing a more holistic understanding of healthcare workforce allocation.

How This Study Might Affect Research, Practice, and/or Policy

This study has the potential to become the basis of policy-making related to the distribution of health workers and provide constructive feedback and strategical insights that could be utilized to decrease the gap between health workers and their maldistribution.

50 INTRODUCTION

51 The landscape of global health is continually evolving, marked by the dynamic interplay between
52 healthcare needs and the availability of healthcare professionals. At the heart of this landscape is the
53 pivotal role of health workers, whose quantity and distribution are essential for effective healthcare
54 delivery¹. The World Health Organization (WHO) since 2005 and aligned with Sustainable
55 Development Goals (SDGs) indicators underscore this significance, particularly after adjusting the
56 need of universal health coverage^{2,3}. Human resources for health, serving as the backbone of health
57 systems, face the persistent challenge of achieving equitable distribution. With its unique
58 geographical and demographic profile, Indonesia exemplifies this struggle, presenting a complex
59 case for the distribution and availability of health workers.

60 Indonesia, the world's largest archipelago and fourth most populous nation, with its approximately
61 17,000 islands, embodies these challenges in distributing its health workforce⁴. The country's vast
62 and varied geography, encompassing remote areas, borders, and small islands, complicates the
63 equitable distribution of healthcare services⁵. Additionally, the decentralized migration of health
64 workers towards urban centers exacerbates the issue, leading to a disparity in healthcare availability
65 between urban and rural or remote regions⁶.

66 The number of health workers is crucial in determining the effectiveness of healthcare delivery⁷.
67 However, the issue extends beyond mere numbers; the distribution of these workers plays a critical
68 role in ensuring that all regions, irrespective of their geographic or demographic characteristics,
69 have access to adequate healthcare services. This challenge is further compounded by the issue of
70 healthcare workforce production in Indonesia, which is not accompanied by equitable distribution⁸⁻
71 ¹⁰. The imbalance in the distribution of health workers, particularly in a geographically diverse
72 country like Indonesia, presents a multifaceted challenge that needs comprehensive analysis and
73 targeted interventions¹¹.

74 The aim of this study is to provide an in-depth analysis of the current state of health workers in
75 Indonesia, with a particular focus on both their quantity and distribution at the district level.
76 Previous reports and research have often overlooked broader regional or national-level
77 assessments¹². This lack of detailed data has been a significant gap in understanding the true extent
78 of the challenge faced by the Indonesian health system. By delving into the district-level dynamics
79 of health worker distribution and quantity, this study seeks to bridge this knowledge gap and offer
80 insights that could inform policy and practice, ultimately contributing to reducing inequities in
81 healthcare access across Indonesia.

82

83 METHODS

84 We gather information from various sources, particularly formal government agencies and
85 ministries that collect data on health resources, both published and unpublished. All the analysis
86 needed will be done in the R using stats and the dineq package.

87 **Definition of Administrative Unit**

88 Indonesia's administrative area is divided into 34 provinces and 514 districts. Districts are
89 categorized as cities (urban areas) or regencies(rural areas), with 416 districts and 98 cities reported
90 in 2022. Health worker data is also aggregated into five major islands: Sumatra, Java, Kalimantan,
91 Bali-Nusa, Sulawesi, and Maluku-Papua. This approach considers that health service coverage can
92 extend beyond district and province administrative boundaries.

93 **Definition and Source of Health Worker Data**

94 Health workers are general practitioners, specialists, dentists, nurses, and midwives. Health workers
95 must have gone through higher education and professional training^{13,14}. This study consolidates all
96 24 categories of specialists into a single group. General practitioners (GPs) practice both in primary
97 and referral care, and between private and public. while specialists primarily operate within
98 hospitals and private practices. Midwives are predominantly employed in primary care.

99 Number of health workers at the provincial-level data is derived from the “*Annual Indonesian*
100 *Health Profile Book*” from 1990 to 2021. District-level data were gathered from the “*Minister of*
101 *Health's Health Resources Database (SISDMK)*”. We extracted SISDMK data on 31 December
102 2022. Data on doctors, dentists, and specialists are supplemented with Data on Members of the
103 Indonesian Doctors Association and Doctors' Registration Data by the Indonesian Medical Council.
104 The Health worker ratio will represent the number of health workers per 1,000 population within a
105 geographic unit. Population estimate data, used as the health worker ratio's denominator, were
106 retrieved from the Ministry of Internal Affairs' GIS data, with the most recent estimates dated 30
107 June 2022.

108 **Benchmark of Health Worker Density**

109 The existing density of health workers will be compared with goals set by Indonesia's Directorate
110 of Health Workforce Planning's Target Document, utilizing Data Envelopment Analysis (DEA) and
111 Stochastic Frontier Analysis (SFA) for target ratio calculations (see Table 1). We will also
112 compared to the World Health Organization (WHO) proposed threshold of health-worker ratio
113 (including doctors, nurses, and midwives) of 4.45 per 1,000 people to meet 80% coverage of the
114 Sustainable Development Goals (SDGs)¹⁵

Table 1. Recommendation of Health Worker density			
Health Worker	National Target	Others Recommendation	Source
GP	1:1000	1:1000	Kumar <i>et.al.</i> , 2018 ¹⁶
Specialist	0.2:1000	1:1000	WHO
Dentist	0.2:1000	0.13:1000	Pandya, <i>et.al.</i> , 2020 ¹⁷
Nurse	2.4:1000	3.3:1000	WHO
Midwifery	2:1000	11.4:1000 (female)	The White Ribbon Alliance. 2017 ¹⁸
All Health Worker	5.8:1000	4.45: 1000	WHO: Global strategy on human resources for health ¹⁹

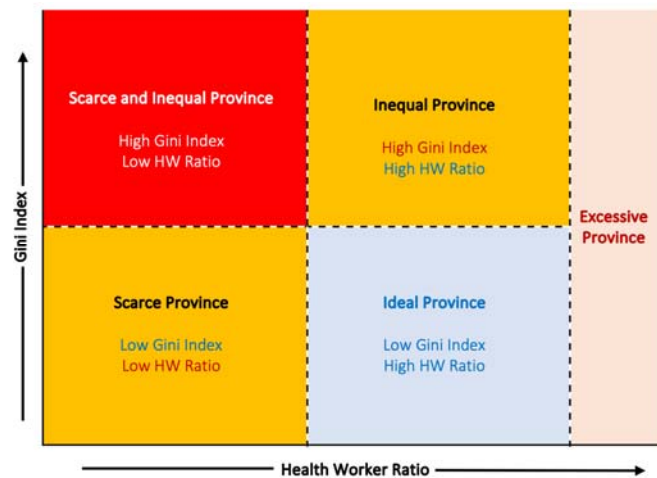

115 **Distribution Analysis**

116 To analyze distribution, we will directly compare ratios between administrative, urban, and rural
117 areas and use the Gini Index, as previously recommended in WHO Measuring Health Worker
118 inequalities^{20 21-23}. The Gini coefficient is a statistical metric obtained from the Lorenz curve,
119 which measures the level of inequality in a distribution. It is expressed as a value between 0
120 (indicating perfect equality) and 1 (indicating perfect inequality). We performed inter-provincial
121 and within-province Gini Index, which has been prevalently used in prior research²⁴⁻²⁷. To further
122 measure inequities between district, the inter-district Gini index will be used in this research^{28,29}

123 **Quadrant Analysis Framework**

124 We made a quadrant analysis to evaluate the two facets of quantity and distribution, as depicted in
125 Figure 1. This method involves plotting provinces on a two-dimensional plane defined by two axes:
126 the Gini Index and the Health Worker (HW) Ratio. The quadrant framework categorizes provinces
127 into four distinct groups based on their position relative to the median values of the Gini Index and
128 HW Ratio. The resulting quadrants are labeled as follows:

- 129 1. **Scarce and Inequitable Province:** High Gini Index and Low HW Ratio, indicating a province
130 with a shortage of health workers and a highly uneven distribution.
- 131 2. **Inequitable Province:** High Gini Index and High HW Ratio, suggesting a province with a
132 sufficient number of health workers but an unequal distribution among the population.
- 133 3. **Scarce Province:** Low Gini Index and Low HW Ratio, pointing to a province with an overall
134 scarcity of health workers but a relatively even distribution among the population.
- 135 4. **Ideal Province:** Low Gini Index and High HW Ratio, representing a province with both a high
136 number of health workers and an equitable distribution.

137 **Figure 1.** A Quadrant Analysis of Gini Index vs. Health Worker Ratio

138 This framework is intended to identify and visualize the disparities in health worker distribution
139 across provinces. In line with the nature of Indonesia, decentralization pushes the provincial
140 government to achieve equal growth within the province. This approach will inform policymakers
141 at the provincial and national levels by highlighting areas of need and guiding targeted
142 interventions.

143

144 **RESULTS**

145 **Quantity of Health Workers**

146 Indonesia's health workforce comprises 1,046,640, averaging 3.84 per 1,000 people nationally but
147 varying widely across districts (0.31 to 19.08). Nurses are the largest group (531,214; 1.95 per
148 1,000), followed by midwives (300,756; 1.10 per 1,000), general practitioners (145,602; 0.38 per
149 1,000), specialists (41,893; 0.15 per 1,000), and dentists (27,177; 0.1 per 1,000). The nurse-to-
150 doctor ratio is about 2.17 nationally.

151 In examining the distribution of health workers between urban and rural areas in Indonesia, clear
152 disparities are evident across different medical professions. General Practitioners (GPs) in rural
153 areas have a median ratio of 0.27 and an average of 0.31, contrasting sharply with urban areas,
154 where the median ratio is substantially higher at 1.10 and the average is 1.34. The disparity is even
155 more pronounced for dentists; in rural regions, they have a median ratio of 0.05 and an average of
156 0.06, whereas in urban areas, these figures significantly increase to a median of 0.20 and an average
157 of 0.27. Specialists present a similar pattern of distribution. In rural areas, the median ratio for
158 specialists is 0.06 with an average of 0.08, which is markedly lower than in urban areas, where the
159 median ratio rises to 0.35 and the average to 0.42.

160 Rural areas have median ratios of 0.87 for midwives and 1.26 for nurses, which are substantially
161 lower compared to urban areas, where the median ratios are 0.86 for midwives and a significantly
162 higher 3.18 for nurses. Overall, this data underscores a consistent trend of higher health worker

164 For most healthcare worker categories, the distribution is right-skewed, meaning that most rural and
 165 urban areas have lower ratios of healthcare workers, with a few areas having much higher ratios.
 166 The kurtosis values suggest that these distributions are leptokurtic, with a higher peak and heavier
 167 tails than a normal distribution, particularly for GPs and dentists in rural areas and for urban nurses.
 168

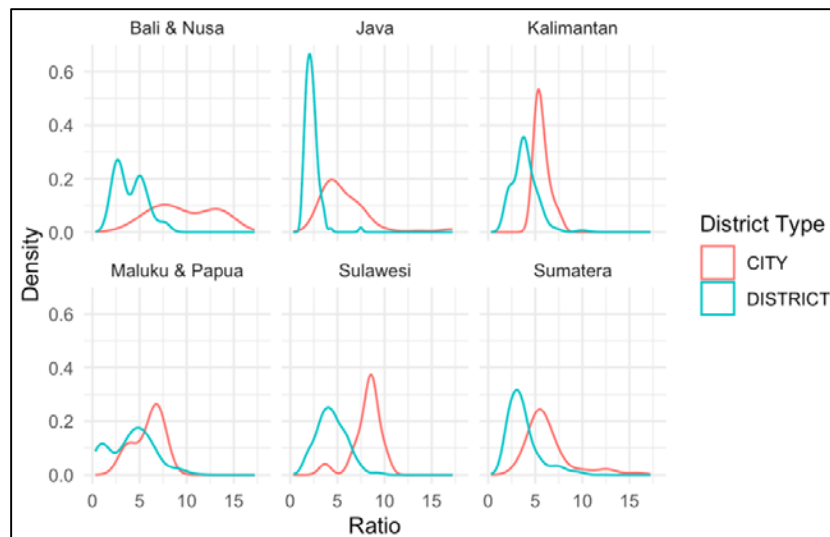

Table 2. Descriptive Statistics of Health workers density in Indonesia

	Min	25%	Median	Mean	75%	Max	Skewness	Kurtosis
NATIONAL								
Population	25,015	425,613	1,056,965	1,283,218.61	1,865,647	5,385,219	2.73	10.41

Nurse Ratio	1.55	2.54	3.18	3.61	4.16	12.03	1.46	3.01
Healthworker Ratio	3.1	4.97	5.94	6.64	7.62	19.08	1.53	2.88

169 **Island and Provincial Levels Distribution**

170 Table 3 shows the distribution of health worker ratios across Indonesian islands and provinces. The
 171 data reveals several disparities, with Java having the lowest health worker ratio (3.06 per 1,000
 172 population) and Sulawesi the highest (5.04 per 1,000 population). Each island presents a distinct
 173 health worker composition; notably, Bali Nusa Tenggara and Java have the highest GP ratios at
 174 0.45 and 0.38, respectively. Java leads in specialist and dentist ratios (0.17 and 0.1) but has the
 175 lowest ratios for nurses and midwives (1.69 and 0.72), suggesting an imbalance in healthcare
 176 worker distribution.

177 Provincially, Aceh has the highest health worker ratio (7.68), followed by DKI Jakarta (6.23). The
 178 lowest ratios are in West Java (2.44), Banten (2.69), and Central Java (2.83). Bali's GP ratio (0.98)
 179 is close to the WHO-recommended physician ratio, and DKI Jakarta has the highest specialist ratio
 180 (0.63). These figures indicate uneven healthcare resource allocation, with certain areas having a
 181 high concentration of healthcare professionals and others facing severe shortages.

182 **Figure 2. Regional Health Worker Distribution by City and District: A Density Plot Comparison.** This set of
183 density plots compares the distribution of health worker ratios across different Indonesian regions, distinguishing
184 between city and district types. Peaks represent the most common ratios within each region, with red lines indicating
185 city densities and blue lines for districts. The plots reveal variations in distribution patterns, with some regions showing
186 distinct differences between city and district densities, potentially indicating disparities in health worker allocation.
187

188 The density plot at figure 2 presents a comparative analysis of health worker (HW) ratios across
189 different islands and regions in Indonesia, categorized by city and district types. In Bali and Nusa,
190 the HW ratio distribution for cities and districts demonstrates a bimodal pattern, indicating two
191 distinct groupings of HW ratios within each category. Java's distribution exhibits a stark peak for
192 cities at a lower HW ratio, suggesting a uniformity in lower ratios among cities, in contrast to
193 districts that show a broader, more varied distribution.

194 Kalimantan's data suggests a single, similar peak for both cities and districts, with cities having a
195 marginally higher peak, implying a slight concentration of HW ratios within city areas. Meanwhile,
196 Maluku & Papua reveal a significant contrast between cities and districts; cities have a flatter, more
197 varied HW ratio distribution, whereas districts show a distinct, narrow peak at higher ratios.
198 Sulawesi's density plot indicates a single peak for both city and district types, with the city peak
199 being more pronounced, pointing towards a more consistent HW ratio among Sulawesi cities.

200 Sumatera's analysis reveals a higher peak for districts compared to cities, suggesting a trend towards
201 higher HW ratios within district areas. Overall, the graph indicates significant regional variability in
202 HW ratios, with certain trends such as the bimodal distribution in Bali & Nusa and the contrasting
203 distributions in Maluku & Papua standing out.

204

Table 3. Healthcare Workforce Distribution by Region: Population-to-Health Worker Ratios in Indonesia.

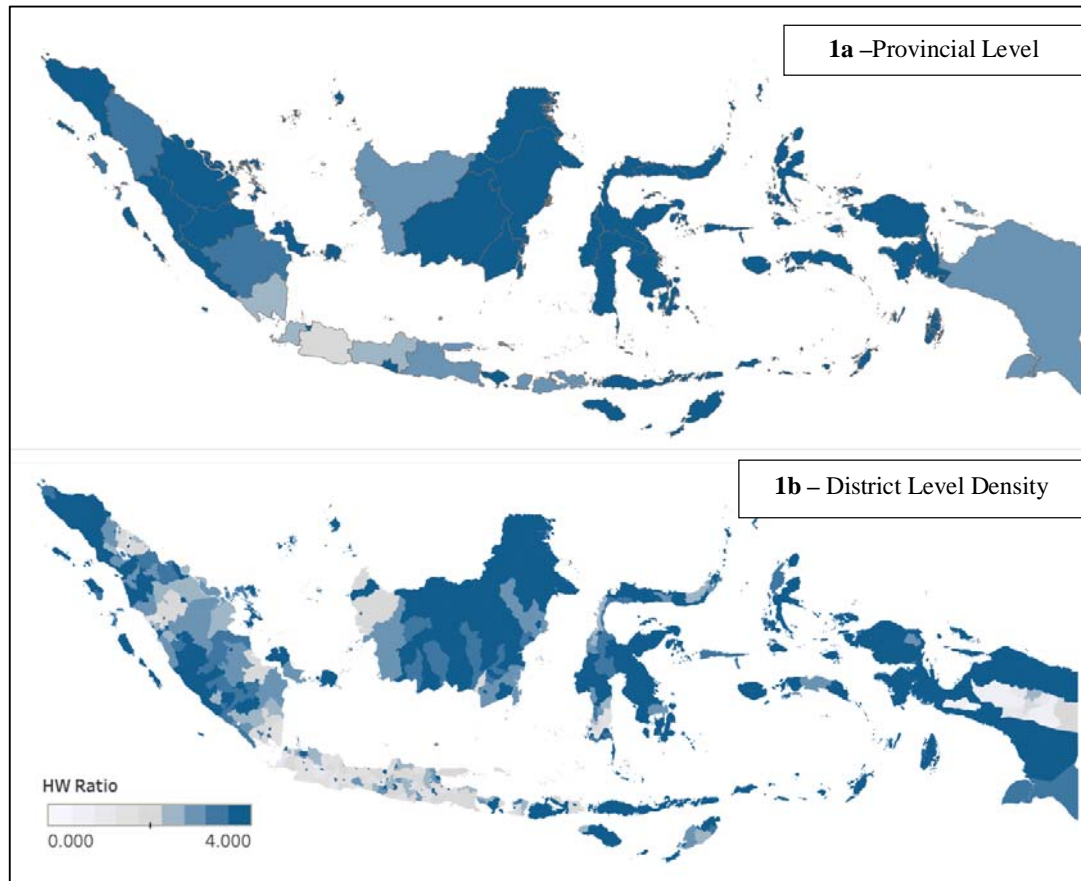

The ratios are calculated per 1,000 population.

205 District-Level Distribution

206 Figure 3 shows a distinct change in the mapping of health workers between the provincial-level
 207 aggregate ratio(1a) and district-level aggregate ratio(1b), especially in Java Island. Health workers
 208 are concentrated in cities (small areas with a high ratio of health workers), and lack of health
 209 workers in more rural areas in Java. Despite having the largest number of healthcare workers, by
 210 comparing the number to their population, the ratio in most districts in Java remained below
 211 Indonesia and WHO-recommended density (Figure 4).

212

213 **Figure 3. Geographic Distribution of Health Worker Ratios in Indonesia: A Comparative View at Provincial and**
 214 **District Levels.** This map pair illustrates the health worker (HW) ratio across Indonesia's provinces (1a) and districts
 215 (1b). Darker shades of blue indicate higher HW ratios, with the scale ranging from 0 to 4. The provincial-level map
 216 shows broader trends, while the district-level map provides a more granified perspective, revealing significant
 217 variations within provinces.

218 **Figure 4. Population vs. Health Worker Ratio Across Indonesian Regions: Scaling and WHO Standards**
 219 **Compliance.** The scatter plot displays the relationship between the logarithm of the population size and the health
 220 worker ratio for various Indonesian regions. Each point represents a region, with the WHO-recommended ratio as a
 221 reference line. The plot highlights disparities in health worker distribution relative to population, with some regions
 222 significantly above or below the WHO benchmark.

223 The Figure 4 scatter plot displays a wide variance in health worker-to-population ratios. The graph
224 indicates that most regions have health worker ratios below the density target except for a few
225 districts that are also the province's capital. Several regions, particularly in Papua, such as
226 Yahukimo, are identified as lower outliers with a deficiency in health worker density.
227 Districts with a larger population tend to have fewer health workers. A logarithmic trend line fitted
228 to the data demonstrates a decremental trend, suggesting that regions with larger populations tend to
229 have a lower health-worker ratio. The Logarithmic trend line equation quantifies the relationship
230 between the population size and the health worker ratio, $\text{Health Worker Ratio} = -$
231 $1.2749 \cdot \ln(\text{Population}) + 19.004$. The coefficient of determination, R-squared (0.215958).
232 Moreover, the distribution of health worker ratios exhibits right-skewness. This skewness indicates
233 that while most regions are understaffed, a few are exceptionally well-staffed.

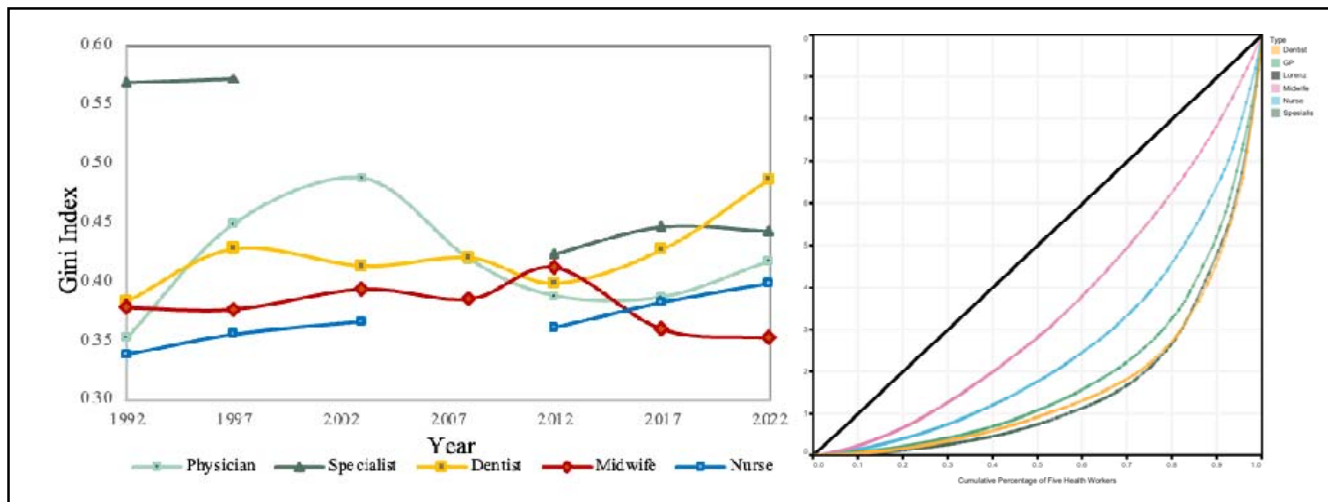

234 **Inequity in Distribution**

235 The Gini Index has demonstrated variable trends over the past three decades, as depicted in Figure 4
236 and Table 4. For General Practitioners (GPs), the provincial Gini Index increased from 0.35 in 1992
237 to a peak of 0.49 in 2003 before declining to 0.39 in 2012 and rising again to 0.42 in 2022. This
238 fluctuation suggests changes in the equality of GP distribution over time. Dentists and nurses also
239 experienced an increase in provincial inequality, with their Gini Indexes rising to 0.49 and 0.40,
240 respectively, in 2022. Midwives, however, showed an improvement in equality from 1992 to 2022,
241 with the Gini Index decreasing from 0.38 to 0.35.

Table 4. Provincial and District-Level Inequality in Health Worker Distribution: Gini Index from 1992 to 2022. This table presents the Gini Index scores for different health worker categories, measuring the inequality in their distribution across provinces from 1992 to 2022 and at the district level in 2022. Data Unavailability is marked as '...'. .

Health worker	Between Province Gini Index							Between District Gini Index 2022
	1992	1997	2003	2008	2012	2017	2022	
GP	0.35	0.45	0.49	0.42	0.39	0.39	0.42	0.46
Specialist	0.57	0.57	0.42	0.45	0.44	0.53
Dentist	0.38	0.43	0.41	0.42	0.40	0.43	0.49	0.52
Nurse	0.34	0.36	0.37	...	0.36	0.38	0.40	0.33
Midwife	0.38	0.38	0.39	0.39	0.41	0.36	0.35	0.31

242
243 Disparities at the district level, recorded for 2022, reveal a more pronounced inequality for health
244 workers than at the provincial level. GPs saw their district-level Gini Index escalate to 0.46, dentists
245 to 0.52, and specialists to the highest at 0.53. In contrast, Nurses and midwives exhibited a reduced
246 inequality at the district level, with a Gini Index of 0.33 and 0.31, respectively, signifying a more
247 between-province inequality rather than relatively equal distribution across districts.

248 **Figure 5. Trends and Disparities in Health Worker Distribution: Gini Index Over Time and Lorenz Curve**
249 **Analysis.** The graph comprises two panels: the left shows the Gini Index for different health worker over 30
250 years, indicating inequality levels within each sector. The right panel's Lorenz Curves visualize the actual
251 distribution equity for these professions Each color represents a distinct healthcare role, ensuring consistency
252 across both visual analyses.

253 Supported by the Lorenz curves, it suggests that the bottom percentage of districts have
254 significantly fewer health workers than would be expected in an equal distribution, especially for
255 GPs, specialists, and dentists. The middle of the distribution for these categories also shows a
256 considerable gap from the line of equality, indicating that the Gini index's sensitivity to the middle
257 distribution reflects the reality of the distribution of health workers. The top district(s) seem to have
258 a disproportionately high number of health workers, especially specialists and dentists, as indicated
259 by the curves' steep rise as they approach 100%.

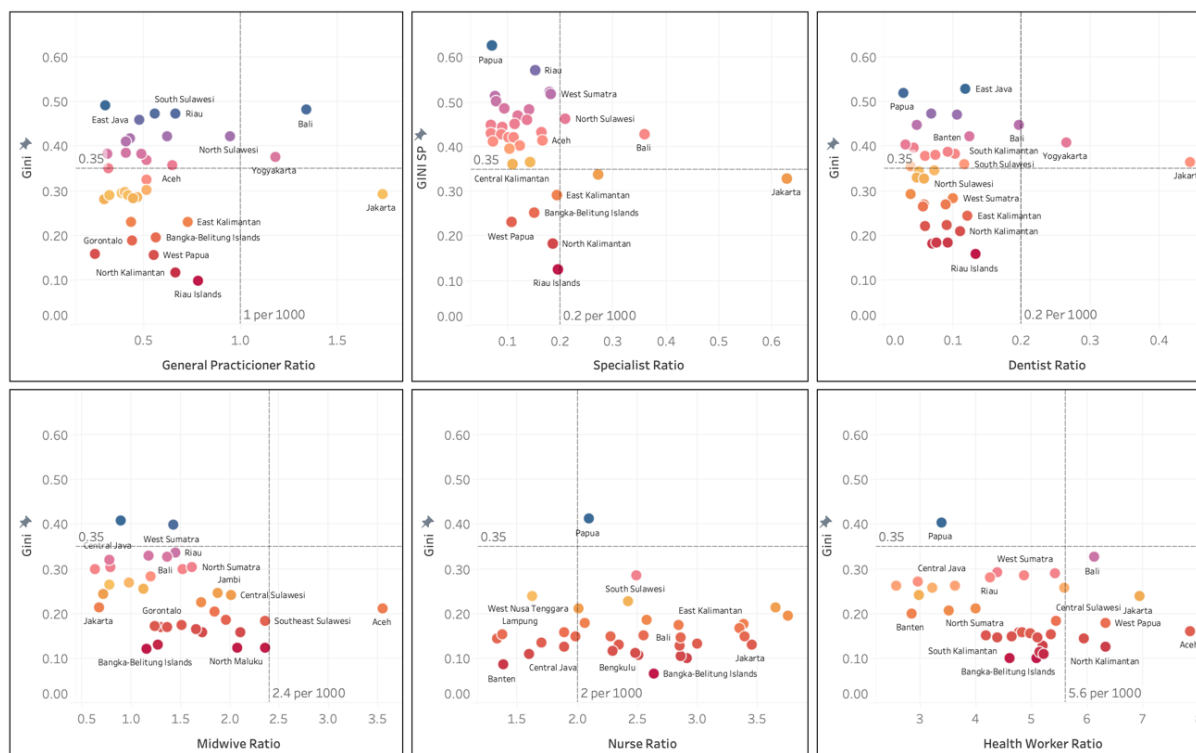

260 **Scarcity and Inequity**

261 Figure 6 offers a visual evaluation of health worker distribution across Indonesian regions. The y-
262 axis is the Gini Index to assess equity in distribution against the x-axis as health worker ratios for
263 various categories, including general practitioners, specialists, dentists, midwives, and nurses.

264 The health worker scatterplot illustrates a widespread distribution across the provinces, with a
265 noticeable lean towards lower ratios, which suggests a general scarcity of health workers in many
266 areas. North Sumatra, in particular, registers a high Gini Index coupled with a low health-worker
267 ratio, underscoring an urgent need for redistribution and an increase in the health workforce.

268 The scatterplots for physicians, specialists, and dentists display a similar pattern, with most
269 provinces failing to meet minimum health worker targets. With exceptions such as Jakarta,
270 Yogyakarta, and Bali that exceed these targets. With its five districts and a substantial physician
271 population, Jakarta is uniquely situated in the bottom-right quadrant, highlighting an oversupply of
272 physicians compared to other regions clustered to the left. Specialists are predominantly located in
273 the upper-left quadrant, indicating a skewed distribution that favors urban centers or provincial
274 capitals and suggests a concentration of specialists in fewer, more developed areas. with

275 Nurses exhibit the most equitable distribution, with only Papua showing significant disparities.
 276 However, the range between the highest and lowest ratios remains considerable, from 1.2 to 3.6 per
 277 1,000. The Midwives ratio plot identifies Aceh as the only province exceeding the equity threshold.
 278 Conversely, Jakarta, typically lower-right in other health worker categories, deviates in the case of
 279 Midwife, showing a surprisingly low ratio and positioning it towards the left quadrant.

280 **Figure 6. Comparative Analysis of Health Worker Distribution Across Regions: Gini Index vs.**
 281 **Various Health Worker Ratios.** (Each scatter plot represents a different category of health workers, with
 282 the Gini index on the vertical axis and the respective health worker ratio on the horizontal axis. Dot
 283 represents a province, with blue shades indicating regions with a higher Gini of health. The dashed line for
 284 Gini referenced 0.35 Gini Ratio, the target for equality. Dashed line for Ratio referenced to national Target
 285 for each health worker)

286 DISCUSSION

287 Quantity of Health Workers

288 Indonesia's archipelagic geography, with its varied terrain and areas isolated by mountains and
 289 oceans, adds to the distribution challenges. Among its 80,000 villages, over 20,000 face
 290 geographical difficulties that obstruct access to healthcare. As of 2022, Indonesia's health-worker
 291 ratio is 3.84. The threshold set by WHO to achieve 80% Universal Health Coverage is 4.45—
 292 requiring an additional 166,000 health workers to surpass the 4.45 threshold.³⁰ Indonesia's lack of
 293 active GPs and Specialists requires attention (0.64 physicians per 1,000 population). Low compared
 294 to other LMIC Nations such as India (0.73 per 1,000), China (2.4 doctors per 1,000), and other
 295 ASEAN Countries (Singapore (2.29), the Philippines (0.6), and Malaysia (1.54).)³¹. Indonesia must
 296 add up to 100,000 physicians to meet the threshold.^{17–20}

298 **Decomposition of Inequity**

299 Contrary to the general perception of Java being saturated with health workers. By numbers, Java
300 has the most healthcare workers, but Java has the lesser density of total health workers, mainly
301 caused by the low number of nurses and midwives. Java is the only island with a midwives ratio
302 lower than 1 and a nurse ratio lower than 2 per 1000 population. However, Java is also the island
303 with the highest ratio of specialists (0.17), while Maluku and Papua had a ratio lower than half of
304 Java's (0.8).

305 Most islands have nearly reached the WHO threshold, with only Java (3.52) and Sumatra (4.42) still
306 below it. However, the high population on these islands significantly affects the national average of
307 health workers. None of the islands have yet met the Indonesian Government's threshold of 5.8
308 health workers per 1000 population, with Sulawesi coming closest at 5.2.

309 The key issue lies in the composition of health workers. Java faces a shortage of nurses and
310 midwives despite having a relatively high number of doctors, though still below the threshold. In
311 contrast, islands outside of Java have a relative abundance of nurses and midwives but a scarcity of
312 doctors.³² This imbalance in the distribution of health workers can be addressed through aggressive
313 policy measures and enhanced nurse education, as demonstrated by China's experience. In China,
314 around 2003, the ratio of nurses to physicians was quite low. However, recent data indicates a
315 significant improvement, with the ratio rising from 1 nurse per 1000 population in 2003 to 4.1
316 nurses per 1000 population in 2018.³³

317 There is a profound disparity between urban and rural areas. Up to 50% of the total GP was in the
318 City, despite the city population being only 20% of the total Population. That's also happening in
319 India, where Out of all qualified workers, 77.4% were located in urban areas, even though the urban
320 population is only 31% of the country's total population. Cities exhibit higher mean ratios across all
321 healthcare workforce categories. Like other low- and lower-middle-income nations, the city tends to
322 have a more significant health worker density.^{23,34-42} While still skewed, the midwife and nurse
323 ratios are less severe.⁴³ This finding is consistent with other research that found an uneven
324 distribution of the total health workforce between rural and urban areas.⁴⁴⁻⁴⁶

325 **Inequity Indicator**

326 The overall trend indicates that while some health worker categories, like midwives, have achieved
327 an equal distribution, others, particularly specialists and dentists, face higher levels of inequality,
328 especially considering the district level. This discrepancy is highlighted by the Gini Index
329 differences between the provincial and district levels, with an apparent increase in inequality at the
330 finer scale of districts for most health worker categories.

331 There has been some progress in equalizing the distribution of medical specialists across provinces.
332 The between-provinces Gini Index For Specialists remarkably dropped from 0.57 in 1993 to 0.44 in
333 2022. However, the Inter-district Gini Index is very high at 0.53 in 2022. This implies that

334 specialists are still saturated in the preferable district, huge cities, and the province's capital.^{34,47,48}
335 Measuring only the between-province Gini Index will mask the disparities within provinces and
336 interdistricts.
337 Comparative studies from western China, a less affluent region compared to the eastern and
338 southern parts of the country, exhibit similar inequality trends. The Physician Gini Index here
339 stands at 0.46. The World Health Organization's last published data from 2010 shows relatively
340 more minor interdistrict disparities in China, with a Gini Index of 0.362 for doctors and 0.471 for
341 nurses. In India, these figures are 0.436 for doctors and 0.527 for nurses^{49,50}. The situation in
342 Indonesia contrasts with both China and India, as it exhibits a higher Gini Index for general
343 physicians and specialists than nurses.

344 **Two Faces of Health Worker Problem in Indonesia: Inequity and Scarcity**

345 The quadrant analysis provides a multidimensional view of healthcare workforce distribution across
346 regions. It highlights the areas of need and the complexity of issues like scarcity and inequality that
347 often overlap, making it difficult to discern the underlying causes and appropriate interventions.
348 The upper-right quadrant has a high ratio of health workers, but resources are not evenly spread
349 across the province. Bali serves as an illustrative case within this analysis. For instance, urban
350 centers like Denpasar City might be well-staffed, while more remote areas suffer from a dearth of
351 healthcare professionals. Addressing this imbalance requires policies incentivizing healthcare
352 workers to relocate to underserved areas or increasing the training and recruitment of health
353 workers specifically for these regions.
354 The upper-left quadrant represents a more critical scenario, as seen with East Java and Papua
355 regions. The inequality in their distribution worsens the simultaneously general scarcity of health
356 workers. Such provinces struggle with redistribution because the overall number of health workers
357 is too low to meet even the minimum needs. To mitigate this, a two-pronged approach is essential:
358 boosting the healthcare workforce numbers through training and recruitment and ensuring retention
359 in underserved areas, perhaps through enhanced benefits, better working conditions, or other
360 incentives.
361 From these findings, we can assume that Indonesia faces a challenge in evenly distributing
362 healthcare professionals, with rural areas experiencing more pronounced shortages. To date, health
363 equity hasn't been prioritized as a main criterion for evaluating the success of health programs.⁵¹
364 Policy interventions to incentivize healthcare professionals to work in underserved areas, scaling up
365 healthcare infrastructure³⁵ and education programs to meet the demand in regions with lower
366 healthcare workforce ratios.^{32,52,53}

367

368 WHO emphasizes the necessity of district-level reporting of health worker data. While provincial-
369 level data offers a general overview, it often fails to represent the situation at the district level.
370 High-level aggregated data can obscure crucial specifics about the distribution and availability of
371 health workers at the subregional level⁵¹. The strain from a lack of healthcare workers was apparent
372 during the COVID-19 pandemic. Healthcare services almost collapsed during the pandemic peak.
373 Any decrease in healthcare workers led to longer working hours for the remaining staff. This
374 created a domino effect of increasing health workers' loads⁵⁴. In maternity care, World Bank
375 statistics reveal that maternal mortality rates in Indonesia have persistently remained relatively high
376 from 2017 to 2021 compared to other Southeast Asian countries. A shortage of healthcare
377 professionals is one critical factor influencing the heightened maternal mortality rate in
378 Indonesia^{55,56}. NCD demands a workforce for every step, especially preventive care⁵⁷.
379 Hypertension in Indonesia increased from 25.8% of the population in 2013 to 34.1% in 2018.
380 Notably, many hypertension cases remain asymptomatic, leading to a high prevalence of
381 undiagnosed.

382 **Limitation**

383 During data collection, we found notable discrepancies between the numbers and distribution of
384 General Physicians and Specialists as reported by the medical association, Medical Council, and
385 Ministry of Health. These inconsistencies likely stem from the council's reliance on correspondence
386 addresses rather than the actual practice locations of medical doctors. Ministry of Health data is
387 much more focused on public health center workers. We acknowledge limitations in the IDI data,
388 primarily due to a five-year delay from a patient's death to the data's release.

389 **CONCLUSIONS**

390 The imbalance in the distribution of health workers in Indonesia is a burden for this country.
391 Government policy factors, security, economic conditions, individual characteristics, income access
392 to children's education, knowledge development, and areas with a better socioeconomic scope will
393 be more attractive to health workers, especially specialist doctors.

394 The health workforce improvement agenda must focus on both increasing the number of health
395 worker and distribute it equally to all people. Central government play a huge role in improving
396 health worker production and distribution to area needed, and Local governments play a vital role in
397 healthcare worker retention. Tailor strategies to local contexts, improve working conditions, offer
398 professional development, and create supportive environments. Engage communities to foster
399 belonging, boosting job satisfaction and retention.

Figure 2. Regional Health Worker Distribution by City and District: A Density Plot Comparison. This set of density plots compares the distribution of health worker ratios across different Indonesian regions, distinguishing between city and district types. Peaks represent the most common ratios within each region, with red lines indicating city densities and blue lines for districts. The plots reveal variations in distribution patterns, with some regions showing distinct differences between city and district densities, potentially indicating disparities in health worker allocation.

Figure 3. Geographic Distribution of Health Worker Ratios in Indonesia: A Comparative View at Provincial and District Levels. This map pair illustrates the health worker (HW) ratio across Indonesia's provinces (1a) and districts (1b). Darker shades of blue indicate higher HW ratios, with the scale ranging from 0 to 4. The provincial-level map shows broader trends, while the district-level map provides a more granified perspective, revealing significant variations within provinces.

19 **Figure 4. Population vs. Health Worker Ratio Across Indonesian Regions: Scaling and WHO Standards**
20 **Compliance.** The scatter plot displays the relationship between the logarithm of the population size and the health
21 worker ratio for various Indonesian regions. Each point represents a region, with the WHO-recommended ratio as a
22 reference line. The plot highlights disparities in health worker distribution relative to population, with some regions
23 significantly above or below the WHO benchmark.
24

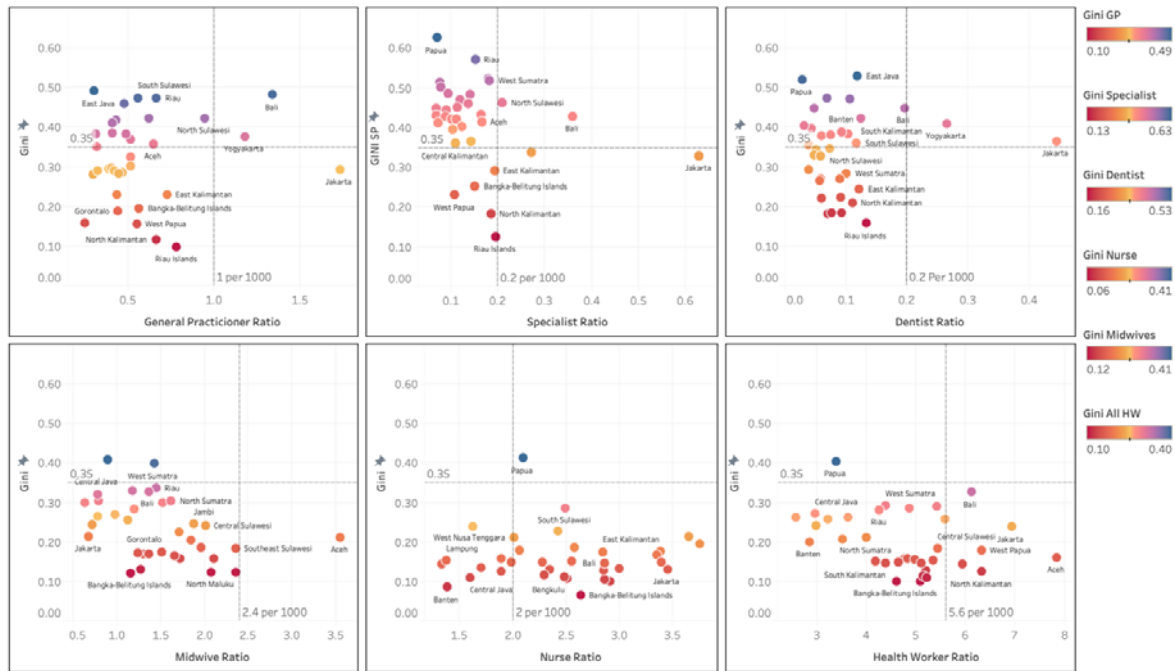

25

26 **Figure 5. Trends and Disparities in Health Worker Distribution: Gini Index Over Time and Lorenz Curve**
27 **Analysis.** The graph comprises two panels: the left shows the Gini Index for different health worker over 30
28 years, indicating inequality levels within each sector. The right panel's Lorenz Curves visualize the actual
29 distribution equity for these professions. Each color represents a distinct healthcare role, ensuring consistency
30 across both visual analyses.

31

32

33 **Figure 6. Comparative Analysis of Health Worker Distribution Across Regions: Gini Index vs.**
 34 **Various Health Worker Ratios.** (Each scatter plot represents a different category of health workers, with
 35 the Gini index on the vertical axis and the respective health worker ratio on the horizontal axis. Dot
 36 represents a province, with blue shades indicating regions with a higher Gini of health. The dashed line for
 37 Gini referenced 0.35 Gini Ratio, the target for equality. Dashed line for Ratio referenced to national Target
 38 for each health worker)
