Abstract

In this study, we assess gender disparities in both citation rates and Altmetric Attention Scores (AAS) within oncology, utilizing a dataset comprising over 600,000 articles from the past 15 years. The analysis focuses on the differential impact of gender on citation metrics and AAS, the latter of which expands the evaluation of research impact beyond traditional citation analysis to include digital engagement metrics such as social media mentions, news coverage, and policy discussions.

Methodologically, the study taps into the Altmetric database, using gender identification tools like the Gender Guesser API to classify articles by the gender composition of their first and last authors. Findings reveal a systemic over-citation of male-first and male-last author pairs (MM), with a mean citation difference (MCD) of +4.7. In stark contrast, female-first and female-last author pairs (WW) experience under-citation, with an MCD of -3.5.

A detailed examination of the Altmetric Attention Score shows that female-first authors receive a 7.19% lower AAS compared to male-first authors, indicating significant gender biases in the broader academic and public engagement. Delving deeper into the components of AAS, specifically news media coverage, reveals that female-first authors are covered 10.9% less in news media, 20.4% less patent references and 33.4% in Weibo mentions than their male counterparts. This disparity is significant and suggests a broader trend of underrepresentation and undervaluation of female-led research in more public-facing and influential media outlets.

These results underscore the persistent influence of gender on the recognition and valuation of scientific contributions within the field of oncology. They highlight the need for academia and publishing entities to implement more equitable practices to mitigate these disparities and ensure a balanced representation and recognition of scholarly work across genders.

Introduction

1 Gender disparities in academia are a global concern, reflecting significant
2 imbalances in the professional landscape of academic and research institutions.¹⁻³
3 Among the various indicators of these disparities, the differences in citation counts—
4 referred to as "citation disparity"—is particularly troubling.^{4,5} This phenomenon not only
5 underscores potential biases in the recognition of scholarly contributions but also
6 directly influences career advancement and the allocation of resources within academic
7 communities.

8 Previous studies have indicated that publications authored by male researchers
9 tend to garner more citations than those authored by females.⁶⁻⁹ This trend can be partly
10 attributed to cognitive biases where male scholars are more likely to recall and cite
11 works by their male peers. Further compounding the issue, research has shown that
12 works with women listed as first or last authors receive approximately 30% fewer
13 citations than comparable works authored by men in similar positions. This discrepancy
14 manifests what is often termed the "Matthew Effect," where male researchers'
15 contributions are seen as more central and pivotal to their fields. In contrast, the
16 "Matilda Effect" describes the relative under-recognition and undervaluation of scientific
17 achievements when women are the principal researchers.¹⁰

18 The persistent citation disparity between male and female researchers has
19 prompted various explanations, including differences in resource allocation for open
20 access publications, collaboration dynamics, academic rank, areas of specialization,
21 and the topics addressed in published works.¹¹⁻¹³ The continuation of these disparities
22 may foster a simplistic view that the scholarly contributions of male and female
23 scientists are fundamentally different. However, this perspective fails to consider the
24 significant evidence of systemic barriers that impede women's progress in academia.
25 Previous research highlights the biases in perceptions of excellence, which can
26 influence opportunities for visibility and advancement provided to individuals.¹⁴

27 While citations are traditionally seen as a key indicator of academic productivity
28 and often serve as a basis for research and academic promotions, the introduction of
29 the Altmetric Attention Score (AAS) provides a more nuanced measure of research

30 impact. This score not only assesses the volume of citations but also evaluates the
31 quality of attention that scholarly articles receive. It includes a range of complementary
32 metrics, such as article downloads, mentions in policies and patents, media coverage,
33 and engagement within professional networks (e.g., reference managers) and social
34 media platforms like Twitter and mainstream media.¹⁵ This expansive approach offers a
35 more comprehensive assessment of an article's influence, presenting potential avenues
36 to explore and address the intricate dynamics of citation and attention disparities in
37 academia.⁸ Despite its potential, AAS remains underutilized in examining gender
38 disparities.

39 In this study, we aim to analyze potential disparities in the Altmetric Attention
40 Score specifically within the field of oncology over the past 15 years, spanning over
41 600,000 articles. We will examine the impact of research publications authored by
42 female first and last authors compared to those authored by males. Furthermore, our
43 study seeks to quantify the extent of over/under-citation in oncology literature, with an
44 additional focus on differences across various subspecialties.

45 **Methodology**

46 **Sample creation**

47 The initial dataset was compiled from the Altmetric database through Application
48 Programming Interface (API) obtained through Drexel University focusing on scholarly
49 published articles that include specific keywords: 'sarcoma', 'radiation therapy', 'stem
50 cell transplant', 'targeted therapy', 'immunotherapy', 'melanoma', 'malignancy',
51 'lymphoma', 'chemotherapy', 'carcinoma', 'neoplasm', 'tumors', 'oncology', 'leukemia',
52 'carcinogenesis', 'metastasis', 'adenocarcinoma', 'squamous cell carcinoma', 'glioma',
53 'myeloma', 'cancer genetics', 'precision medicine', 'cancer screening', 'cancer
54 prevention', 'cancer diagnosis', 'palliative care', and 'cancer epidemiology'. The search
55 was focused on articles published between January 1, 2009, and January 31, 2024.
56 This approach yielded an extensive dataset comprising 652,834 records across the
57 various oncology subfields.

58 In addition to the gender of the authors, our dataset was enriched with a variety of fields
59 to support our analysis. These can be accessed in eMethods.

60 The dataset was rigorously preprocessed to maintain data accuracy and
61 pertinence to our research objectives. This involved normalizing author names and
62 correcting discrepancies within the metadata. To enhance the scope of papers suitable
63 for gender classification based on first names, we utilized the DOI crossref API for
64 comprehensive name citation matching.¹⁶ This process enabled us to associate
65 abbreviated names, often represented by initials in certain journal entries, with their full-
66 name counterparts. For instance, an entry such as L.B. Smith, accompanied by a DOI,
67 was matched to its full form, Laura Bernice Smith, facilitating the application of the
68 GenderGuesser API.¹⁷

69

70 **Name based assignment of author gender categories**

71 In our dataset, we established "author gender categories" based on the first
72 names of the first and last authors of the papers. Using the Gender Guesser API—a
73 commercial tool providing statistical name-gender correlations across 191 countries—
74 we assigned gender to authors whose first names had at least a 99.9% probability of
75 being associated with a particular gender, labeling them as 'man' or 'woman'
76 accordingly.

77 Our comprehensive dataset consisted of 652,843 papers, and we were able to
78 confidently assign gender to both first and last authors in 75.1% of the papers.
79 Furthermore, for 19.2% of the papers, gender could only be ascribed to either the first or
80 last author. Papers were then categorized based on the gender labels of the first and
81 last authors. Those with at first and last author labeled 'woman' were categorized as
82 WW, even if the other authors' genders were undetermined. Conversely, if both first and
83 last authors were labeled 'man', the paper was categorized as MM.
84 It is important to clarify that "author gender category" is a statistical tool and does not
85 necessarily reflect the actual gender identities of the individuals. It is a proxy indicating a

86 correlation between a given name and gender identity as commonly recognized on
87 social media or official documents. The actual gender identity of authors could only be
88 discerned through self-identification or personal knowledge, which lies beyond the
89 scope of an automated analytical process such as ours.

90 Nonetheless, the use of author gender categories serves as a practical
91 approximation for our study since names significantly influence the perception of gender
92 identity. Such perceptions can affect judgments of scientific merit and, by extension,
93 citation practices—regardless of the true gender identity of the authors in question.

94 Furthermore, our study concentrated on the first and last authors due to a well-
95 established norm in life sciences authorship. Typically, the first author of life science
96 articles is the junior author responsible for conducting the research, whereas the last
97 author is usually the senior author who conceptualizes and finances the research.

98

99 **AAS score**

100 For the first part of our analysis, we focused on the Altmetric Attention Scores
101 (AAS) for each publication, analyzing the scores in relation to the gender of the first and
102 last authors. This evaluation was critical to determine if the gender of the authors
103 influenced the amount of attention their research garnered across all altmetric variables.
104 We employed an Ordinary Least Squares (OLS) regression approach to establish a
105 model for investigating the dynamics between the logarithmically transformed AAS
106 (independent variable) and the volume of Dimensions citations (dependent variable). In
107 this construction, we accounted for variables such as the first author's gender, open
108 access (OA) status, and the publication year, enabling a measured examination of their
109 collective influence on the citation count. Our regression framework incorporated an
110 intercept to capture the baseline effect beyond the scope of the explanatory variables. A
111 constant term was introduced, facilitating the interpretation of the model's coefficients
112 with respect to a null baseline of the independent variables. Upon fitting the OLS
113 regression model, we evaluated the statistical significance of each coefficient to

114 determine the impact of gender, OA status, and AAS on the predicted number of
115 citations.

116

117 **Subspecialty Delineation**

118 We compiled a roster of peer-reviewed publications across various oncological
119 subspecialties for analysis, which includes sectors such as breast oncology,
120 gastrointestinal oncology, gynecologic oncology, head and neck oncology, hematology-
121 oncology, neuro-oncology, urological oncology, radiation oncology, general oncology,
122 surgical oncology, and molecular oncology. These journals span the surgical, medical,
123 and scientific domains within cancer research literature. The selection of journals was
124 predicated on the availability of comprehensive data and their respective impact factors.
125 To gauge citation impact, a baseline citation score of 1 was established, reflective of the
126 significance of receiving at least one citation within the first two years post-publication.
127 Each subspecialty was represented by a minimum of three journals. In instances where
128 a journal was relevant to more than one category, it was retained only in the category
129 where it was most contextually appropriate, thus avoiding redundancy. In total, 64
130 journals were classified into eleven categories, with 451,881 total articles from 2009 to
131 2024.

132

133 **Subspecialty Metrics**

134 Calculation of over/under citation was calculated as a percent difference of
135 observed citation from the gender-blind expectations model. Gender blind expectations
136 using generalized additive model on the binomial outcomes [MM, WW] (GAM)
137 previously described was utilized.¹⁸ Briefly, gender blind null model predicts the
138 probability of citations based on publishing journal, categorization as a research, year of
139 publication, combined number of authors in the dataset. For each article, one can define
140 its over/under citation of each author gender category as the percent difference of
141 observed citations from gender blind expectations. The degree to which papers
142 authored by man-man (MM) pairs are over- or under-cited can be quantified using the
143 formula $(oMM - eMM)/eMM * 100$ where oMM represents the actual observed number of
144 citations received by MM papers from the citing articles, and eMM the predicted count of

145 citations for MM papers, as forecasted by the gender-neutral model. Details regarding
146 all these parameters and accompanying tests of significance can be found in
147 documentation of the 'mgcv' package in R.¹⁹

148

149 **Results**

150 A total of 652,843 papers were retrieved using Altmetrics API. The distribution of
151 our gender categories is as follows: 'UU' (unknown-unknown) pairs were the most
152 common at 162,751, followed by 'MM' (man-man) pairs at 157,494, and 'WM' (woman-
153 man) pairs at 92,245. 'WW' (woman-woman) pairs accounted for 61,329 papers, while
154 'MW' (man-woman) pairs were present in 53,461 papers. Papers with one unknown
155 gender paired with a known man ('UM') were 42,678, and those paired with a known
156 woman ('WU') were 25,945. Lastly, 'MU' (man-unknown) and 'UW' (unknown-woman)
157 pairs numbered 36,180 and 20,760 respectively.

158

159 **Gender differences in overall attention and source of attention**

160 The analysis shows a notable difference in the overall Altmetric Attention Score
161 (AAS) and its individual components between women and men serving in the first and
162 last author positions (as shown in Fig 1G for first authors and Fig 1H for last authors).
163 Women in the first author position have a 7.19% lower AAS compared to their male
164 counterparts, a statistically significant difference ($p < 0.001$). The discrepancy is slightly
165 less for last authors, with women exhibiting a 4.9 % lower AAS than men ($p = 0.004$).

166 In terms of individual components measured by different sources of attention,
167 first author women received less coverage by 10.9% in News ($p < 0.0001$), 20.2% in
168 policy discussions ($p < 0.0001$), 20.4% in patent references ($p < 0.0001$), 33.4% in Weibo
169 mentions ($p = 0.05$), and 8.2% in Twitter mentions ($p = 0.001$). Similar trends were
170 observed for women in the last author positions, with overall decreases in mentions
171 across news ($p = 0.03$), policy discussions ($p < 0.001$), patents ($p < 0.001$), Wikipedia
172 references ($p < 0.001$), and citation counts ($p < 0.001$). Across all metrics within altmetrics,
173 no single metric showed a statistically significant preferential mention of female first or
174 last authors over males.

175 For the longitudinal analysis from 2009 to 2024, there has been an upward
176 trajectory in engagement metrics across both gender lines. Nonetheless, our data
177 reveal a persistent gender gap in the frequency of academic mentions. On social media,
178 particularly Twitter, male authors outpaced female authors with an average of 12.5
179 mentions compared to 8.6 ($p < 0.001$) (Fig 1A). A similar trend emerged in news media,
180 with male authors receiving slightly more mentions than female authors by a margin of
181 0.2, peaking notably in 2022 (Fig 1C). Further examination of altmetric score highlights a
182 gender discrepancy favoring male first authors, who scored an average of 1.8 points
183 above female first authors (Fig 1E).

184 Within last authorship, male last authors were more frequently mentioned in
185 Twitter conversations, averaging 13.2 mentions in contrast to 9.5 for their female
186 counterparts ($p < 0.001$) (Fig 1B). This gender imbalance was echoed in news coverage,
187 where male last authors were mentioned nearly twice as often as female last authors
188 (0.8 vs 0.42 mentions, respectively; $p < 0.001$) (Fig 1D). Additionally, the altmetric scores
189 for 2024 reinforced this trend, with male last authors achieving scores averaging 12.5,
190 significantly higher than the 8.1 average for female last authors ($p = 0.03$) (Fig 1F).

191

192 **Citation Imbalance by Specialty**

193 The proportion of papers in each author category (MM, WW, MW, WM) can be
194 seen in Figure 2B as a function of publication. Note that percent of WM authorship
195 represents the lowest total category with minimal growth from 2009 (10.2%) to 2024
196 (13.0%). Similarly, WW represent a small proportion of authorship, with minimal growth
197 from 2009 (9.5%) to 2024 (14.4%) (Fig 2B).

198 The representation of WW authorship in oncology subspecialties has relatively
199 modest growth, with the exception of Breast Oncology and Gynecologic Oncology,
200 where there has been a marked increase in female authorship. Gynecologic Oncology,
201 for instance, nearly doubled its representation of women authors, escalating from 17.7%
202 in 2009 to 35.4% in 2023. Urologic Oncology, though starting with a lower baseline, saw
203 its female authorship proportion rise from 3.1% to 5.2% in the same timeframe,
204 reflecting a measurable and consistent growth. Overall, none of the subspecialties

205 experienced a decline in women's authorship, with the majority showing at least a
206 nominal increase over the past fourteen years, as detailed in Figure 2A.

207 Figure 2D elucidates distinct inter-journal variations in the representation of
208 women-first and women-last authorship across various oncology subspecialties.
209 Notably, while the *Journal of Neuro-Oncology and Neuro-Oncology* maintain a
210 comparable average of 13% for women authorship, *World Neurosurgery* exhibits a
211 markedly lower figure, with women authors constituting less than 4.5% of its
212 publications. In the realm of surgical oncology, the *Annals of Surgical Oncology*
213 demonstrates a consistent inclusion of women in authorship roles, unlike the *World*
214 *Journal of Surgical Oncology* and the journal *Surgical Oncology*, where women's
215 representation is significantly lower. These observations underscore the potential
216 influence of individual journal policies and editorial practices on the prevalence of
217 women's authorship within their publications.

218

219 **Citation Imbalance**

220 Our analysis of citation trends among gender combinations revealed strong
221 evidence of gender bias. The MM combination has a striking over-citation value within
222 oncologic academia, with a mean citation difference (MCD) of 4.7 (Figure 2C). In
223 comparison, WW papers were found to be under-cited, with a MCD of -3.5.
224 Furthermore, this trend generally persisted among all four gender combinations (Figure
225 2E). WW papers were the only cohort to experience under-citation (MCD -3.6).
226 Interestingly, MW papers experience the highest over-citation with a MCD of 6.3 in
227 comparison to MM with a MCD of 4.7. However, the overall pattern of WW papers being
228 routinely under-cited and male authorship facilitating increased citation was observed.
229 Dissecting these trends further, Figure 2F,G reveals that these citation gaps are not
230 uniform across all subfields. In urologic oncology, MM experiences over-citation rate of
231 0.32%, while female-authored works are significantly undercited by 24.2%, bringing the
232 total gender-based citation gap to 24.5%. Oncology stands out with the largest disparity,
233 where MM pairs receive 19.0% more citations than anticipated, and WW pairs 22.9%
234 fewer, cumulatively presenting a stark citation gap of 41.9%.

235 Nonetheless, the fields of gynecologic oncology and radiation oncology present
236 an exception to this pattern. In these subspecialties, both WW and MM authorship
237 configurations receive citations at rates exceeding expectations, with MM pairs at 59.5%
238 and WW at 39.7% in gynecologic oncology, and 47.6% for MM and 39.5% for WW in
239 radiation oncology. These exceptions indicate a potential for field-specific dynamics
240 influencing citation practices, which may override the broader gender-based trends
241 observed in citation behavior.

242
243

244

245

246 **Discussion**

247 In our study encompassing an extensive dataset of 652,842 published
248 manuscripts between 2009-2024, we sought to evaluate gender differences in
249 proportions of papers published, citation metrics, and AAS across the field of oncology,
250 an area which has not been extensively reported on in the literature. The data from our
251 study reveal that publications authored by men, particularly those with male first and last
252 authors (MM), are consistently cited more frequently than those authored by women.
253 This trend was observed across various oncology subspecialties but was most
254 pronounced in general oncology, where the gender citation gap was the largest. This
255 could reflect a combination of cognitive biases where scholars are more likely to cite
256 works from their male peers, as well as structural biases within the research community
257 that might favor male principal investigators for clinical trials, research topics, or
258 methodologies more commonly pursued by male researchers.

259 Interestingly, our results also showed that mixed-gender authorship pairs,
260 specifically male first and female last authors (MW), experienced higher citation rates
261 than expected. This suggests that the presence of a male author in a prominent position
262 may mitigate some of the negative impacts of gender bias on citation rates. However,
263 the fact that women-women (WW) pairs were consistently under-cited, even more so

264 than mixed pairs, underscores the specific challenges faced by female scholars,
265 especially when they occupy both pivotal roles in research authorship.

266 The under-citation of female-authored papers is troubling not only because it
267 reflects bias but also because it directly impacts the visibility and influence of women's
268 research contributions. Lower citation rates have significant implications for career
269 advancement, funding opportunities, and academic recognition. The "publish or perish"
270 culture in academia places substantial weight on citation metrics. These metrics can
271 influence a variety of professional outcomes, including graduate opportunities, funding
272 success, career positions, awards, distinctions, and the critical processes of tenure and
273 promotion.²⁰ These trends have been substantiated by research, including a critical
274 evaluation of the Altmetric Top 100 lists from 2015 to 2019, which demonstrated a
275 significant citation gap disadvantaging female authors.²¹ Furthermore, an in-depth
276 examination of more than 5000 articles from high-impact medical journals showed a
277 recurring pattern of fewer citations for papers where women serve as first or last
278 authors.⁷ Particularly pronounced was the finding that papers with women occupying
279 both the first and last authorship positions experienced a citation rate halved compared
280 to their male counterparts. These studies echo our own findings, pointing to an average
281 gender citation gap of -8 in articles authored by women when contrasted with those
282 authored by men, highlighting a critical issue that the academic community must
283 address to promote equitable recognition of all researchers, and not just in theory but in
284 practice.

285 Our study examined direct consequences of under citation utilizing the AAS,
286 which has provided a detailed perspective on how research is perceived and valued
287 across different platforms, including social media, policy documents, and news outlets.⁸
288 The AAS findings are indicative of a persistent gender gap when it comes to the visibility
289 and recognition of academic work. Our results indicate that papers with women in the
290 first author position were found to have an AAS that was 7.2% lower than those of their
291 male counterparts—a significant difference that carries important implications for the
292 reach and impact of their research. Last authors who are women also faced a deficit,
293 with a 5.7% lower AAS compared to men.

294 More specifically, female first authors received lower coverage by 10.9% in news
295 outlets, 20.2% in policy discussions, and 20.4% in patent references, with even more
296 pronounced disparities observed in social media platforms such as Weibo and Twitter.
297 Similar patterns were noted for women in last author positions, with reduced mentions
298 and references across all examined media, suggesting a broad-based undervaluation of
299 their contributions. In addition, over the fifteen-year period from 2009 to 2024, while we
300 saw an overall increase in engagement metrics for academic work, the data underscore
301 a gender divide, with male authors consistently receiving more mentions across the
302 majority of platforms.

303 While there is a scarcity of research on AAS gender disparities specifically within
304 oncology, other medical disciplines have begun to shed light on this phenomenon.
305 Studies from cardiology, for instance, reveal that articles authored by women first
306 authors are significantly less likely to achieve high AAS compared to those by men.⁸
307 Yet, when women occupy senior authorship roles, this gap in AAS does not seem to
308 persist, and the difference in AAS between WW and men-men MM authored articles is
309 not significant.

310 With the rise of social media as a pivotal platform for the dissemination of
311 scientific and medical knowledge, the relevance of AAS and their associated sources of
312 attention has surged, given their established correlation with citation rates. In the field of
313 oncology, this correlation has been particularly noted in randomized phase III cancer
314 trials, where a higher AAS is often an indicator of a greater number of citations.^{22,23} This
315 trend is mirrored in gynecologic oncology research, where a robust positive relationship
316 has been identified between median citation counts and median AAS.²⁴ Moreover,
317 evidence suggests a growing link between an article's presence in high-impact journals
318 and its AAS, implying that such publications tend to receive more media attention and,
319 consequently, a higher citation rate. This correlation underscores the importance of
320 amplifying the presence of female-authored research in prominent journals to bolster
321 visibility and citation impact.²⁵

322 This study faces several limitations. Primarily, the reliance on an online database
323 to determine the gender of authors introduces the possibility of misclassification and
324 incomplete data due to some authors being labeled as "unknown" or "excluded." In

325 addition, this approach does not account for the nuances of gender identity and self-
326 identification, which transcend binary male or female categories. Such complexities are
327 beyond the capacity of bioinformatical tools to discern, as they typically rely on name-
328 based gender inference. The study also does not delve into the specifics of topics or
329 publication types—such as videos or manuscripts—which can significantly influence
330 AAS. For instance, studies have found that content related to treatment and quality of
331 life, or the use of video abstracts, tends to attract more online engagement.²⁶ Future
332 research into the impact of gender on AAS might consider these factors more closely,
333 including examining the gender makeup of citation sources and the proportion of female
334 authorship in papers, which could provide deeper insights into the nuances of academic
335 influence and recognition.

336 Despite existing challenges, there are several effective measures that can be
337 implemented to narrow the persistent gaps in citation rates and AAS related to gender
338 disparities. Establishing transparent and equitable citation practices is crucial. Journals
339 can play a significant role by encouraging or requiring the inclusion of diverse work,
340 particularly by integrating more women and underrepresented groups into their reviewer
341 and editor pools to enhance visibility. Additionally, there should be a deliberate effort to
342 promote the work of female researchers through social media and press releases,
343 which could involve partnerships with academic institutions to showcase a broader
344 range of research through various communication channels and support of open access
345 publishing. Furthermore, funding bodies are encouraged to consider AAS and citation
346 data within the context of existing biases when assessing grant applications. By
347 developing policies that account for the influence of gender bias on these metrics, it's
348 possible to reduce their impact on funding decisions and support fairer research
349 evaluation practices.

350 In conclusion, this manuscript has highlighted significant gender disparities in
351 citation rates and AAS across various fields within oncology. Our findings highlight a
352 systemic issue where female-authored research is under-cited and receives less
353 attention compared to male-authored work, potentially impacting career advancement,
354 funding opportunities, and academic recognition for women in science. As we advance,
355 it will be essential to continue monitoring these metrics and implementing robust policies

356 that not only recognize but actively combat the biases that perpetuate gender disparities
357 in academic research.
358

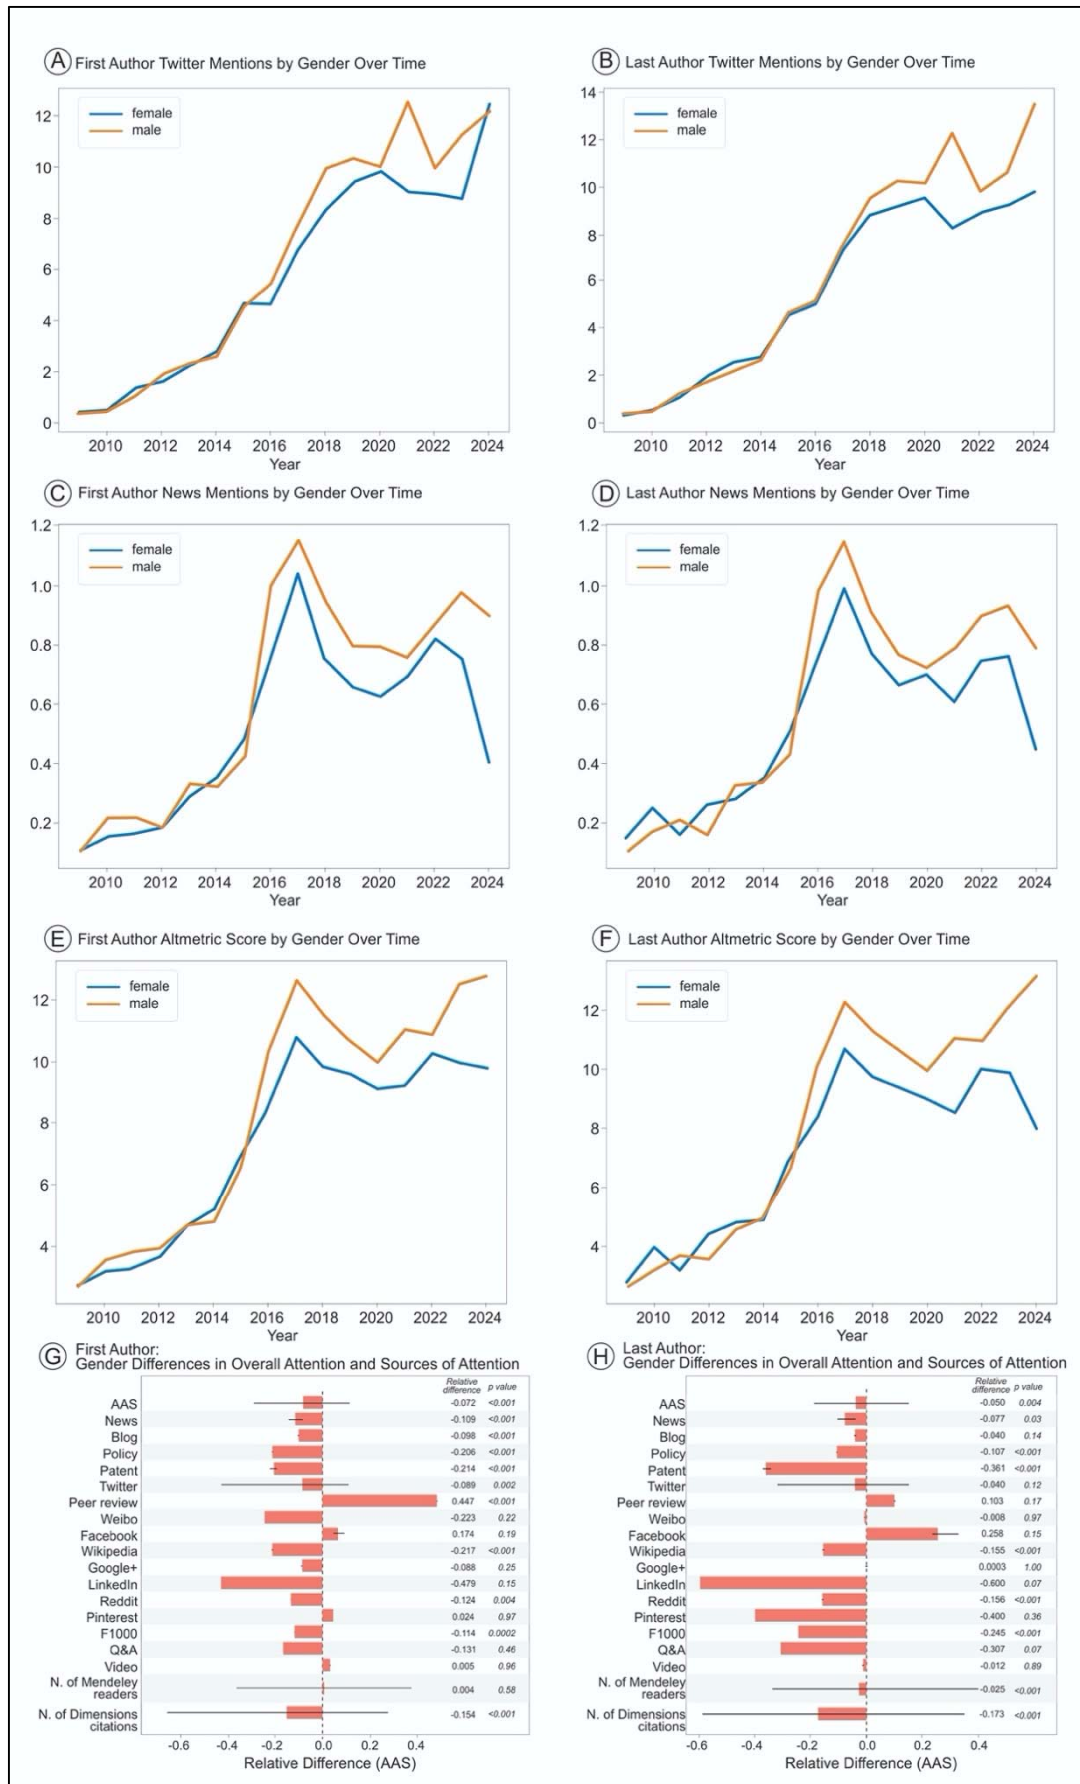

Figure 1. Analysis of Almetric Attention Scores (AAS) over time and by source of attention, including: A) first author Twitter mentions by gender over time; B) last author Twitter mentions by gender over time; C) first author news mentions by gender over time; D) last author news mentions by gender over time; E) first author AAS by gender over time; F) last author AAS by gender over time; G) relative differences in AAS for woman first author compared to male first author by specific source of attention; H) relative differences in AAS for woman last author compared to male last author by specific source of attention.

Figure 2. Analysis of gender combinations (gender of first author and gender of last author) and citations, including: A) proportion of WW papers over time by oncologic specialty; B) gender combination proportions over time (including WW, WM, MM, MW); C) over/under citation by gender combination (including MM and WW); D) proportion of WW papers over time by oncologic specialty (including specific high impact journals within each category); E) over/under-citation by all gender combinations (including WW, WM, MM, MW); F) over/under-citation by oncologic specialty and gender combination (including MM and WW); G) graph illustrating imbalance between mean difference in citations for WW versus MM with each point illustrating a specific journal which is color-coded according to the oncologic field in which it belongs. MM = male first author/male last author; MW = male first author/women last author; WM = women first author/male last author; WW = women first author/women last author.
