Supplemental Information

Methods

Viruses: The viruses used for the comparative studies included SARS-CoV-2; 2019-nCoV/USA-WA1/2020 (MN985325.1), SARS-CoV-2/Munchen-1.1/2020/929; SARS-CoV, Urbani; and MERS-CoV-hNIS, and MERS-CoV Hu/Jordan-N3/2012 (KJ614529); EMC/2012 (JX869059.2). Virus stocks were prepared in Vero E6 cells and sequence confirmed by PCR and/or Sanger sequencing. Plaque assays were performed in Vero E6 cells. A manuscript is in preparation with a more detailed description of virus propagation and plaque assays (Klimstra, W., Duprex, P.).

Dynamic aerosol exposures: Aerosol exposures were conducted using the Automated Bioaerosol Exposure System (ABES) or AeroMP (Biaera Technologies, Hagerstown, MD) exposure management platform inside a Class III biological safety cabinet operated under negative pressure. The 3-jet (C3), 6-jet Collins (C6) or Aerogen Solo (AS) nebulizers were used for generation of aerosols. Aerosol sampling was performed with an all-glass impinger (AGI)-4 (Ace Glass, Vineland, NJ) or SKC Biosampler (SKC Inc, Eighty Four, PA). Aerosol particle size was determined using an Aerodynamic Particle Sizer solely or with the addition of a diluter (TSi, Shoreview, MN).

SARS-CoV-2 quantitative Real-Time Reverse Transcriptase-Polymerase Chain Reaction. Extracted nucleic acid samples were tested for SARS-CoV-2 by qRT-PCR following a previously published assay. Two RT-qPCR monoplexes targeting the N and ORF1b were used. The primers and probes used to amplify the ORF1b gene are: forward primer [5’-TGGGGYTTTACRGGTAACCT-3’]; reverse primer [5’-AACRCGCTTAACAAAGCACTC-3’]; and probe [5’-FAM-TAGTTGTGATGCWATCATGACTAG-TAMRA-3’]. The N gene was amplified using the following primers and probe: forward primer [5’-TAATCAGACAAGGAACTGATTA-3’]; reverse primer [5’-CGAAGGTGTGACTTCCATG-3’]; and probe [5’-FAM-GCAAAATTGTGCAATTGGC-3’]. Briefly, a 20 µl reaction mixture was prepared using the iTaq Universal probes One-Step kit (BioRad, Hercules, CA), according to manufacturer instructions: 10 µL of reaction mix (2x), 0.5 µL of iScript reverse transcriptase, 1 µL primers (10µM), 0.5 µL probes (10µM), 4 µL of extracted RNA and 3 µL of water. The RT-qPCR reactions were conducted using the thermocycler StepOnePlus™ Real-Time PCR System (Applied Biosystems). Reactions were incubated at 50°C for 5 min and 95°C for 20 sec followed by 40 cycles at 95°C for 5 sec and 60°C for 30 sec. Serial dilutions of the RNA extracted from a virus stock with known concentration was included for generation of a standard curve and to estimate the amount of targets in the experimental samples.

Scanning Electron Microscopy: 5 mm x 2 mm hydroxyapatite (HAp) discs (Clarkson Chromatography) were incubated with 750 µL of each virus sample in DMEM media
within a 24-well plate for 30 minutes. Sterile forceps were used to transfer each disc to 2.5% glutaraldehyde in deionized water for 12 hours. Samples were further fixed in 1% osmium (VIII) oxide in 100 mM PBS for 30 minutes then rinsed in deionized water 3x. Samples were prepared for scanning electron microscopy by drying in successive increasing concentrations of ethyl alcohol (from 25%-100%) each for 10 minutes and critical point dry in a Tousimis® Autosamdri-814 dryer before mounting with carbon tape, double carbon sputter-coating in a Cressington® 208HR sputter coater, and imaging at 3 kV in a Hitachi S-3400 SEM.

**Analysis:** Significance determined in **Figure 1** by Mann-Whitney and Brown-Forsythe tests and nonlinear regression analysis in **Figure 2** performed in GraphPad Prism version 8.4.1.
