

Mandated Bacillus Calmette-Guérin (BCG) vaccination predicts flattened curves for the spread of COVID-19

Supplementary Materials

Supplementary Results 1. Weighting country data based on underreporting index

We estimated a linear mixed model that was identical to that used in our main analysis, except that reporting index was included as a weighting factor in the model. Results were consistent with our main analysis, demonstrating that our effects are robust against differences in reporting quality across countries (see Table S3).

Supplementary Results 2. Controlling for the total number of tests

We estimated linear mixed models that were identical to those used in our main analysis, except that the total number of tests for each country was included as a covariate in each model. Results were consistent with our main analysis, demonstrating that our effects are robust against differences in testing availability across countries (see Table S4).

A. Confirmed cases

64 countries were included in this analysis. We found a significant main effect of day, $b = 0.117$, $p < .001$, reflecting an exponential increase in cases over time. This increase was qualified by a significant interaction between day and the contrast between current and non-current BCG policy. Specifically, the growth rate of COVID-19 cases was marginally slower in countries with mandated BCG vaccinations, compared to countries without mandated BCG vaccinations, $b = -0.036$, $p = .021$. Countries that once had such policies but terminated them before 2000 were not significantly different in growth rate from those that never instituted mandatory BCG vaccinations, $b = -0.013$, $p = .619$. In sum, our focal effect was no different with total tests added as a covariate. See Table S4-A for full regression table.

B. Deaths

60 countries were included in this analysis. We found a significant main effect of day, $b = 0.149$, $p < .001$, reflecting an exponential increase in cases over time. This increase was qualified by a significant interaction between day and the contrast between current and non-current BCG policy. Specifically, the growth rate of COVID-19 cases was marginally slower in countries with mandated BCG vaccinations, compared to countries without mandated BCG vaccinations, $b = -0.056$, $p = .014$. Countries that once had such policies but terminated them before 2000 were not significantly different in growth rate from those that never instituted mandatory BCG vaccinations, $b = -0.033$, $p = .373$. In sum, our focal effect was no different with total tests added as a covariate. See Table S4-B for full regression table.

Supplementary Results 3. Robustness check with 15-day time window

To test the robustness of our models, we conducted a second set of analyses, only using the first 15 days of data (rather than the first 30). The 15-day cutoff allowed us to examine more exclusively than the 30-day cutoff the very first phase of the outbreak in each country. Because our primary analysis included only countries that reported at least 15 days of eligible data, the same set of countries was included here (see Table S1 for full list for each analysis). All patterns were identical to the primary analyses.

A. Confirmed cases

We found a significant main effect of day, $b = 0.163$, $p < .001$, reflecting an exponential increase in cases over time. This increase was qualified by a significant interaction between day and BCG policy. Specifically, the growth rate of COVID-19 cases was significantly slower in countries with mandated BCG vaccinations, compared to countries without mandated BCG vaccinations, $b = -0.052$, $p < .001$. Countries that once had such policies but terminated them before 2000 were not significantly different in growth rate from those that never instituted

mandatory BCG vaccinations, $b = 0.015$, $p = .504$. In sum, our focal effect was no different with a shorter time window. See Table S5-A for full regression table and Figure S1-A and B for growth curves.

B. Deaths

Similarly, we found a significant main effect of day, $b = 0.190$, $p < .001$, reflecting an exponential increase in deaths over time. This increase was qualified by a significant interaction between day and BCG policy. Specifically, the growth rate of COVID-19 deaths was significantly slower in countries with mandated BCG vaccinations, compared to countries without mandated BCG vaccinations, $b = -0.070$, $p = .002$. Countries that once had such policies but terminated them before 2000 were not significantly different in growth rate from those that never instituted mandatory BCG vaccinations, $b = 0.010$, $p = .795$. In sum, our focal effect was no different with a shorter time window. See Table S5-B for full regression table and Figure S1-C and D for growth curves.

Supplementary Results 4. Testing cultural dimensions

We first dummy-coded BCG status (BCG currently mandated vs. BCG not currently mandated). We then tested each variable that varied significantly as a function of BCG policy status as an additional covariate in our primary models, to test our key finding (the interaction between day and the primary BCG contrast) would be observed after controlling for the cultural dimension. Since the cultural indices were not available for all the countries included in the main analyses, and moreover, different indices were available for different sets of countries, each cultural dimension was analyzed separately so as to preserve the maximal number of countries.

A series of t-tests revealed that countries that currently mandate BCG (compared to all others) were significantly lower in individualism, whereas they were higher in power distance (Table S6). Tightness/looseness did not significantly vary between countries with and without mandated BCG policies.

A. Confirmed cases

To test whether the cultural dimensions shown to vary between the countries that differed in the BCG policy status might explain the effect of BCG policy status, we repeated the analyses reported in the main text with each of the cultural dimensions included as a covariate (see Tables S7-A and S8-A). 65 countries were included in each analysis. The key interaction between day and BCG policy status (contrasting countries that currently mandate BCG with those that do not) remained statistically significant when either individualism or power distance was added as a covariate.

B. Deaths

We conducted the same two analyses to test whether individualism and power distance qualified the effect of BCG on the increase in deaths over time (see Tables S7-B and S8-B). 64 countries were included in each analysis. The key interaction between day and BCG policy status (contrasting countries that currently mandate BCG with those that do not) remained statistically significant when either individualism or power distance was added as a covariate.

Supplementary Results 5. Testing the effect of policy age

We examined the age of the BCG policy in each country that currently mandates vaccination. Among those countries that have mandated BCG, there is a variation in how old the policies are. It might be expected that the older the policies are, the more effective they are to reduce the rate of spread of COVID-19. However, there was no evidence for this conjecture.

A. Confirmed cases

A linear mixed model was conducted to test whether there was any effect of BCG policy age on the exponential increase in confirmed COVID-19 cases. This analysis included 48 countries. We used the same model specifications as in our primary analyses. Both day and policy age were centered so that main effects could be interpreted as differences at the mean

day of the growth curve. The model included day, policy age, the interaction of day with policy age, and all covariates: median age, population density, net migration, log population, and GDP per capita. All covariates were standardized.

The model revealed no effect of policy age on the growth rate of cases, $b = 0.004$, $p = .557$ (see Table S9-A).

B. Deaths

An identical model was conducted to test whether there was any effect of the age of the policy on the exponential increase in COVID-19 related deaths. This analysis included 47 countries. There was no effect of policy age on the growth rate of deaths, $b < -0.001$, $p = .990$ (see Table S9-B).

Supplementary Results 6. Predicting US cases and deaths if BCG were mandated

We estimated the numbers of confirmed cases and deaths estimated for the U.S. if it had instituted a mandatory BCG vaccination policy decades ago. To do this, we used the "predict" function in R. In particular, we plugged the value of each predictor for the U.S. into the regression equation. The value for day was set at 14.5, corresponding to the centered value of day 30, the final U.S. data point (on April 1 and March 29, 2020, for the analysis of confirmed cases and deaths, respectively). The BCG vaccination policy status was set to be equal to the countries that currently have mandatory BCG vaccination policies. The values for all other predictors were taken from available current U.S. values. The output gives the predicted number of cases (using the confirmed cases model) and deaths (using the deaths model) after natural log transformation. We thus calculated the numbers on their original scale by exponentiating our predicted value. This analysis applied to the number of cases yielded a predicted value of 11.141, which translates to 68970.547 cases (compared to the actual 213372 cases reported in the US by April 1). This analysis applied to the number of deaths yielded a predicted value of 6.448, which translates to 631.684 deaths (compared to the actual 2467 deaths reported in the US by March 29).

Table S1. List of all countries included in analysis of cases and deaths, with the date set as day 1 in each country. Countries with dates entered in columns 2 and 3 are those included in our analysis of cases and deaths, respectively.

Country	Date of first 100 cases	Date of first death	BCG policy status
Afghanistan	3.27.20	3.22.20	Currently mandated
