Supplemental data

**Supplementary Figure 1. Gating strategy for flow cytometry analysis.** (A) Gating strategy for the main peripheral blood lymphocytes. Lymphocytes were selected from a forward scatter-area vs side scatter-area dot plot, and single cells were subsequently selected in a forward scatter-area vs forward scatter height dot plot. Then, T cells were selected by CD3+ expression and CD8+ cytotoxic and CD4+ helper T cells were identified by a CD8 vs CD4 dot plot. NK cells were identified as CD3- and CD56+ and/or CD16+ lymphocytes and CD56brightCD16-, CD56dimCD16+ and CD56-CD16+ functional subsets were selected in a CD16 vs CD56 dot plot. B cells were selected as CD3-CD19+ lymphocytes. For plasma cells, a forward scatter-area vs side scatter-area dot plot, followed by single cells selection was performed. Then, CD19+ cells were gated as B cell lineage and CD20-CD38bright were defined as plasma cells. (B) Gating strategy for main maturation stages of B lineage. Starting from CD19+CD20+ B cells, transitional B lymphocytes were selected as CD27-CD10+ cells. CD27+ and CD27- cells were selected in a side scatter-area vs CD27 dot plot. From the CD27- subpopulation we identified, in an IgD vs IgM plot, the naïve (IgD+IgM- or IgD+IgM+) and IgD-IgM- subsets; from the CD27+ subpopulation and in the same IgD vs IgM plot, we identified the unswitched memory (IgD+IgM+), IgM-only memory (IgD-IgM+) and class-switched memory (IgD-IgM-) subsets. (C) Gating strategy for circulating Tfh lymphocytes. Circulating Tfh lymphocytes were selected from CD4+ T cells by double positive staining of CXCR5 and PD-1. This population was analyzed for CCR7 expression.
Supplementary Figure 2. viSNE analysis of lymphocyte subpopulations in COVID-19 patients. Plots show distribution of lymphocyte subpopulations in a representative healthy donor (left) and COVID-19 patient (right). viSNE maps (Cytobank) are shown in single colour according to expression of selected marker.
**Supplementary Figure 3. Memory B cell subpopulations are related to severity in COVID-19 patients.** Boxplots show percentage of distinct memory B cell subpopulations (left: unswitched memory B cells; right: IgM-only memory B cells) in healthy donors (white) and COVID-19 patients with different severity degree: mild (blue), moderate (yellow) and severe (red).
