Simpact Cyan 1.0

The models in this study were developed with Simpact Cyan 1.0, an open-source framework for individual-based modeling of transmission, diagnosis and treatment of HIV [8]. Simpact Cyan 1.0 models each individual in a population, as well as the sexual relationships between individuals. Birth, mortality, the formation and break-up of relationships as well as HIV transmission, diagnosis and treatment are represented by events. The risk that an event takes place at a certain moment is represented by its hazard function. Simpact Cyan 1.0 implements models in continuous time, i.e. each time an event happens the models are updated. Also a generic STI co-factor effect on HIV is implemented. Furthermore, parameters can be changed during the simulation to simulate interventions. More details on Simpact Cyan 1.0 are available in [8] and from http://www.simpact.org/.

Weibull distribution

Because we simulate a population of only men, where no birth events can happen, we have to avoid in the simulation that a lot mortality events caused by AIDS happen. We can implement this like indicated in Figure S1.

The population pyramid for males from Belgium in 1980

(https://www.populationpyramid.net/belgium/1980/) was used to fit the Weibull survival distribution. Figure S2 shows the survival distribution for real age and simulation age.

^{*} diana.hendrickx@uhasselt.be

Figure S1. Real age versus simulation age in this study.

Figure S2. Weibull survival distribution for real age (left) and simulation age (right).

In the parameter configuration file, this is implemented as

- mortality.normal.weibull.scale = 106
- mortality.normal.weibull.shape = 5

Other parameter settings

Table S1. Parameter settings used for all scenarios in this study.*: only for scenarios including an STI co-factor effect.

Intervention events

Table S2 summarizes the intervention events for simulating the increased ART coverage since 1994, and the increase in sexual risk behaviour with ART coverage.

Table S2. Intervention events for simulating the increased ART coverage since 1994, and the increase in sexual risk behaviour with ART coverage. CD4 treshold: the parameter monitoring.cd4.threshold, if a person's CD4 count is below this threshold, he will be offered ART; diagnosis.baseline: baseline value in the hazard for a diagnosis event; formation alpha_12: the parameter formationmsm.hazard.simple.alpha_12 in the hazard for a relationship formation event, corresponding to a weight for the number of relationships the men in the relationship have. This parameter only changes for the scenarios with increased risk behaviour.

year	\mathbf{time}	CD4 threshold	diagnosis.baseline	formation $alpha_12$
1994	24	200	-1.5	initial value $+ 0.05$
1996	26	230	-1.25	initial value $+ 0.1$
1998	28	260	-1	initial value $+ 0.15$
2000	30	290	-0.75	initial value $+0.2$
2002	32	320	-0.5	initial value $+ 0.25$
2004	34	350	-0.25	initial value $+0.3$
2006	36	380	0	initial value $+0.35$
2008	38	410	0.25	initial value $+0.4$
2010	40	440	0.5	initial value $+ 0.45$
2012	42	470	0.75	initial value $+0.5$
2014	44	500	1	initial value $+ 0.55$

Generation of Figure 4

For each of the three scenarios (STI-nBC, nSTI-BC, STI-BC) 30 simulations with the fitted parameters were run. For each simulation, and for each person with date of seroconvertion between 1984-2007, we determined the first HIV RNA at 9-27 months after seroconvertion (red dots in Figure S3, each dot represents a person). A curve of the mean log10 SPVL (black line in Figure S3 over time was generated by fitting a cubic spline through the red dots, in analogy to Figure 1A in Gras et al [6]. This was repeated for all 30 simulations. Figure 4 in the main text represents the median and 100% percentile of the 30 splines.

Figure S3. First HIV RNA at 9-27 months after seroconversion for each person with date of seroconversion between 1984 and 2007 (red dots) for a single simulation. Black line: cubic spline fitted through the red dots, representing the mean log10 SPVL over time.
