

## S5 appendix - Community outreach and educational program

Among all the factors that favor the occurrence of dengue, the greatest cause is the large amount of waste in the urban environment, since it favors the formation of mosquito breeding sites.<sup>1</sup>

The participation of the community in the reduction of mosquito breeding sites of *Aedes aegypti* is critical for SIT programs to be more effective.<sup>2,3</sup> Thus, educational programs that inform and mobilize positive actions of the population can contribute to the prevention of dengue and other vector borne diseases.<sup>4</sup>

An educational program integrates the NVC male mosquito intervention plan and focuses on the importance of knowledge in the fight against the *Aedes aegypti* mosquito. These actions occurred during the period of the field study (2017-2019) in Jacarezinho, and included several activities with municipal schools, community centers and local authorities. As part of the educational program, approximately 800 children from four public schools in the study areas (treated and control) participated in playful activities on the biology and history of *Aedes aegypti*, prevention methods and presentation of the NVC method. In addition, these schools were monitored for the presence of *Aedes aegypti* (ovitrap), and regular meetings were held with school directors, pedagogues and teachers in order to inform them of the results found.

Other activities included guided tours of the laboratory where NVC mosquitoes were maintained. This event was offered to 80 students from different schools of Jacarezinho that were also participants of SESC Integral education program of the city.

In addition to the activities for children, several lectures were held at the city's Higher Education Institutions, such as the State University of Northern Paraná and the Federal Institute of Paraná, as well as offering training courses for the endemic agents of the Municipal Sanitary Surveillance. Together with the José Richa Youth Center, charitable and awareness-raising activities were carried out for students of this institution and their families.

The program also included active participation in community events such as village membership meetings and local volunteer organizations (Rotary Club).

During the weekly visits for the collection and installation of the ovitrap in the residences, the distribution of informative pamphlets to the residents was carried out. A local radio station reported daily messages encouraging mosquito prevention, also announcing a free of charge call phone number for information and questions about the field study.

Finally, together with Jacarezinho Department of Agriculture and Environment, the Integrated System for Selective Waste Collection in Jacarezinho was started. At the same time, an outreach work was carried out to inform the population about the importance of proper waste management and disposal, and how this could positively impact the reduction of mosquito breeding sites.
