15 **Introduction**

16 The first wave of the COVID-19 pandemic posed challenges for the provision of abortion
17 care in Europe. Reallocation of resources, redeployment of staff, and social distancing
18 requirements all introduced new barriers to in-person clinic visits.^{1,2}

19 Countries differed in their policy responses to these new challenges. Great Britain expanded
20 remote access to medication abortion, allowing teleconsultation with providers, and
21 mifepristone and misoprostol to be provided by mail.³⁻⁵ France extended the ability to take
22 abortion medications at home following an in-person visit with a healthcare professional
23 from 7 weeks to 9 weeks of gestation.⁶ Germany allowed mandatory pre-abortion
24 counselling to take place by phone or video teleconsult instead of in person.⁷ Most other
25 countries, however, made few changes to medication abortion service models and continued
26 to require fully in-person provision, despite calls from human rights groups to prioritize
27 patient safety and expand remote access.^{7,8}

28 We assessed whether demand for online medication abortion changed significantly in ten
29 countries after implementation of stay-at-home orders intended to reduce the spread of
30 COVID-19 in Europe, using online medication abortion request data from Women on Web,
31 a non-profit organisation that provides telemedicine medication abortion services up to 10
32 weeks of gestation.⁹

33 **Study Design and Methods**

34 We examined data from Women on Web, a non-profit organization that provides medical
35 abortion services in Europe up to 10 weeks' gestation via online telemedicine.⁹ We obtained
36 the daily number of requests from ten countries between January 1st, 2019 and June 1st, 2020

37 (the last day that lockdown measures were lifted in a country included in the analysis). Our
38 analytic sample includes eight countries: Germany, Hungary, Italy, Malta, The Netherlands,
39 Northern Ireland, Portugal, and Great Britain. WoW does not accept consultations from all
40 countries in Europe, because abortion is legal and normally relatively accessible in most
41 places. Among those countries that WoW does serve, some have only a few consultations
42 requests over the course of a year. We excluded countries that had too few requests to
43 reliably detect differences in request numbers between the ‘before’ and ‘after’ periods (i.e.
44 fewer than 10 expected requests in the ‘after’ period). We also excluded Spain, because the
45 Spanish Government censored the WoW website during the study period and so no requests
46 could be made,¹⁰ and Poland because the number of requests made to WoW has been
47 unstable since the beginning of 2020.

48 We analyzed trends in these requests using a regression-discontinuity design.¹¹ For each
49 country, we include data from 1st January 2019 to the date that lockdown measures were
50 lifted in each country. We designated a ‘before’ period, which began on 1st January 2019
51 and ended on the date that each individual country’s government issued their first ‘stay-at-
52 home’ directive. The one exception was Germany, where the ‘before’ period begins on 1st
53 January 2020, due to the fact that WoW did not accept consultations from Germany in until
54 late 2019. The ‘after’ period began the first day after the ‘stay-at-home’ directive was issued
55 for each country, and ended on the first day that the directives were eased in each country.
56 We incorporate a discontinuity for each country for the dates on which stay-at-home orders
57 were in place. To allow sufficient power to detect differences, our analysis included only
58 countries that had at least 10 total expected requests in the “before” period based on
59 baseline trends. As only Malta did not issue a population-wide directive, we instead used the

60 date that the Maltese government issued a directive to close public places as the discontinuity
61 point.¹²

62 Our aim was to test whether the rate of Women on Web requests significantly changed in
63 the “after” period. We fit separate generalized linear models (GLMs) to each country’s daily
64 requests from the beginning of the “before” period until the date stay-at-home measures
65 were lifted. Each country’s model incorporated a dummy variable taking the value of 1 for
66 days in the “after” period, where the stay-at-home order was in place. For Northern Ireland,
67 both the null and discontinuity models included a dummy variable indicating the period after
68 11th April 2020, when Northern Ireland’s service model changed due to legalization of
69 abortion.¹³

70 To determine the functional form of each country’s GLM, we first fit a Poisson model with
71 a log link and assessed goodness of fit using a chi-squared test. For any countries with a poor
72 Poisson model fit ($p < 0.05$), we refit a Negative Binomial GLM to account for over-
73 dispersion and reassessed fit. This resulted in well-fitting models ($p \geq 0.05$) for all countries.
74 For a single country, our Poisson GLM can be formalized as

$$75 \quad \log(cases_t) = t + x_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma^2) \quad (1)$$

76 while the corresponding null model is written as

$$77 \quad \log(cases_t) = t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma^2) \quad (2)$$

78 where t represents days, $cases_t$ is the number of Women on Web requests on day t , and
79 and x_t takes values of 0 or 1, depending on whether stay-at-home restrictions for that
80 country are in place on day t .

81

82 We include an additional term in the models for Northern Ireland due to the change in
83 abortion legalization. The Poisson GLM model for Northern Ireland can be formalized as

$$84 \quad \log(\text{cases}_t) = t + x_t + z_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma^2) \quad (3)$$

85 where z_t takes values of 0 or 1, depending on whether day t falls before 11th April, 2020.

86 The corresponding null model is

$$87 \quad \log(\text{cases}_t) = t + z_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma^2). \quad (4)$$

88 **Results**

89 We refer readers to Figure 1 and Table 1 in the main paper for presentation of our main
90 results. Here, we provide a supplementary figure to illustrate our methods. Figure S1 lends
91 intuition to the regression discontinuity model for a single country, and illustrates Hungary's
92 significant increase in cumulative WoW requests after implementation of the stay-at-home
93 request, compared to the expected number requests under the null model.

100

101 **Figure S1**

102 Left panel: The daily number of requests for Hungary since January 1, 2019. Requests on
103 dates without stay-at-home restrictions are black; requests on dates with restrictions are
104 orange. The blue line shows the model fit without discontinuities (the null model), and the
105 green line shows the model fit with the stay-at-home discontinuity. Right panel: The same
106 data, shown in terms of cumulative requests since 1st January, 2019. The pink lines are 250
107 Monte Carlo simulations from the null model. These corroborate the likelihood-ratio test
108 and suggest the observed rate of requests in Hungary is inconsistent with the null model.
109 The model with a discontinuity fits the data well, as measured by a chi-squared goodness-of-
110 fit test ($p > 0.05$).
